Provability Logic

An Investigation of the Relationship Between Modal Logic and Arithmetics

1 Introduction

{chap:intro}

Skriv kort hvad projektet omhandler og opris de vigtisge resultater
The bibliography of this project consist of a wide range of logical, mathematical and philosophical texts that in one way or another has a connection to of is referenced in the project. The main source for this project is Smorynski 1985

1.1 Notation

We denote the non-negative integers with ω; i.e $\omega = \{0, 1, 2, 3, \ldots\}$, and $\omega \times \omega = \omega^2$ and so on. Subsets of ω will be denoted by $A, B, C \ldots$ and arbitrary sets will be denoted by $\Gamma, \Phi, \Theta \ldots$. Lower case Latin letter a, b, c and x, y, z will denote integers, and $\vec{x}$ will be shorthand for $x_1, \ldots, x_n$. Further recursive functions will be denoted by $\varphi, \psi, \vartheta, \ldots$, the graphs of recursive functions will be denoted by τ, ξ and ζ . Functions that are primitive recursive will be denoted by $f, g, h, \ldots$.

We will further introduce a system of arithmetics called *primitive recursive arithmetics* (From now on shorten to **PRA**) and the formulas of this system will be denoted with F, G and G.

$\varphi(x) \downarrow$ will denote that $\varphi(x)$ is defined and $\varphi(x) \downarrow = y$ denotes that $\varphi(x)$ is defined and has value y. $\varphi(x) \uparrow$ denotes that $\varphi(x)$ is undefined. $\mathrm{dom}(\varphi)$ and $\mathrm{im}(\varphi)$ denotes the domain and image of $\varphi(x)$. A few special functions have their own symbols: S for the successor function, Z for the zero function and P for the projection. The formulae of the language **PRA** will be denoted by F, G and H.

Relations will be denoted by R and $<, >, \leq, \geq$ will be used in the usual sense on integers.

We will use the standard symbols of propositional logic $\wedge, \vee, \rightarrow, \neg$. Further we will sometimes use $\exists$ and $\forall$ in the metalanguage of modal logic, and use them in the language of first-order arithmetics. The differences of these two uses should be clear from the context. We will argument the propositional logic with the modal

unary connective $\square$ and its dual $\lozenge := \neg\square\neg$. We will denote modal formulas by the greek letters $\alpha, \beta, \gamma, \sigma$. The symbol $\mathcal{H}$ will denote a Hintikka frame which is a tuple $\langle W, R \rangle$ where W is a set of "nodes" and R is a relation on W and $\mathcal{K}$ will denote a Kripke model, which is a Hintikka frame with a valuation ϕ on.

1.2 Historical Introduction

Humans have been interested in numbers and calculation with these since before the beginning of history; i.e arithmetics.

1.2.1 Modal Logic

The Greek philosopher Aristotle did try to develop some kind of modal logic about necessary and possibility in both his logical work *De Interpretatione* and in his *Metaphysic*.

With our modern eyes his thoughts about nessaration and possibility seems a bit confusing. But he gets some implications about these notions right. A good overview of this part of his logical work can be found in Lemmon 1977 and in **det polske værk** In the late antiquity and the middle ages there was done some work building on Aristotle earlier work.

The next big step for modal logic came in the enlightenment when the rationalist philosopher Gottfried W. Leibniz came up with the idea of possible worlds. Leibniz thought that we live in the best possible world, since it is this world God has chosen to create. With this idea of a metaphysical possible worlds, it was possible to make a clear definition of when a proposition is necessary true; and a proposition is necessary true, if it is true in all possible worlds. But Leibniz did not any further works on modal logic as a whole.

Modern modal logic is said to be started by Clarence Irving Lewis. He set out to develop a formal system without the paradoxes of materiel implication. This led to his development of a wide range of different modal logical system in the first part of the 20th century. His method was syntactical, since there were yet to be develop a "smart" semantic for modal logic. But in the start of the 20th century, C. I. Lewis had started the modern modal logic, and a lot of other philosophers and logicians began to have an interest in the subject.

In the 1950s there had been a lot of research into the syntax of modal logic. But there was still not a clear definition of the semantics of modal logic, even though philosophers and logicians still had the intuitive definition of necessary true from Leibniz. The answer came in the late 1950s, when the philosophers and logicians Jaako Hintikka and Saul Kripke developed the concept of a Kripke

model.[1] Hintikka came up with the idea of a frame; i.e a pair $\langle W, R \rangle$ where W is a set of worlds and R is an arbitrary relation on these. With this construction it was possible to explain for a given world, what other worlds was accessible to it; i.e possible worlds for it. Kripke came up with the same idea, but added a valuation function to the frame, which to each formula of the language ascribed a set of worlds in which it was true. This construction made it possible for Kripke to prove some completeness results about modal logics.

When the concept of the Kripke model became wider known, it started a *Golden* age of research in modal logic. A lot of completeness results about different modal logic was proven in the 1960s and early 1970s; including the weak completeness theorem for the logic that would later be known as provability logic; this was done by Krister Segerberg without him having knowledge of what the interpretation of this logic could be.

A deeper look into the development of modal logic can be found in Goldblatt 2003.

1.2.2 Arithmetics and Recursion Theory

Even though humans have been using arithmetics for millennials, it had not been axiomatized.

It was first in the second half of the 1800s there was a development in the axiomatization of aritmethics. Richard Dedeking and Giuseppe Peano developed axioms system for arithmetics, these was later evolved into was today is known as the Peano axioms for arithmetics.

Another important achievement at the turn of the century, was David Hilbert's proof that the consistency of Euclidean geometry could be proven by proving that arithmetics was consistent. **Hans geometri værk** This was one of the first steps in what later would be known as the Hilbert program. The Hilbert program was not really a program until the end of 1920, where it became clear that its goal was to prove that the *ideal* transfinite mathematics was consistent, and that the proof of this should be conducted in a *real* finite mathematics system.

An example of such a finite system could be the *Primitive recursive arithmetics* that was developed by Toralf Skolem; the definition of this system will be given in the next chapter. This system can be seen as a (induction-wise) weaker version of Peano aritmetics. Tait argues that such a system fulfills the finitist conditions of the Hilbert program. This system will be the main system of this project and the definition of it will come in the next chapter.

Another (mostly historically) important mathematical system of arithmetics was the one developed by Bertrand Russell and Alfred North Whitehead in their work:

---

[1]They were not alone in this development. But for simplicity sake **ja**

Principia Mathematica. The goal of this work was somewhat different than the one of the Hilbert program. Russell had a thesis that shortly (and not the most precis) says that all of mathematics could be reduce to logic. In Kantian terms he thought that mathematics was analytical *a priori*.

In 1931 Kurt Gödel's paper: *Über formal unentscheidbare Sätze der Principia Mathematica und verwandter Systeme I* it was shown that the system of Russell and Whitehead was not complete, and under the assumption that the system was consistent that it could not prove its own consistency. This result can be generalized to systems strong enough to do simple arithmetic. The original proof was build on the system of Russel and Whitehead and had a assumption of ω-consistency. This was a blow to the Hilbert program, since the result showed that the goal of it could not be fulfilled. Later on John Barkley Rosser**Ref** improved the result so that it consistency was enough.

Later on in the 1930s Gödel extended the primitive recursive function to the recursive functions. A few different definitions of intuitively computable functions was set forward by Kleene, Turing and Church and it was shown that all these different notions of intuitively computable functions gave rise to the same class of functions.

This lead Church to state the so called *Church-Turing Thesis*, that states that this class of functions are the computable functions.

1.2.3 Provability Logic

The first time that someone made a connection between these two different areas of mathematics was Kurt Gödel in his very short paper: {^{a}sdf}. Here we saw the intuitionist's laog, bla bla.

After Löb's derivability conditions was found and after the develpment of the semantics of modal in the 1960s, it became clear that there was a connection between the logic that Segerberg had proven to be weakly complete and the proof predicate from arithmetics.

This lead to research done in different places around the from, from The Netherlands, Italy and the United States. It was clear early on that if α was a theorem of provability logic, then for all interpretations of α in a fragment of arithmetics was also a theorem of this fragment; but the other way was harder to show. In the same time there was proven a number of important theorems about provability; one of these, called the Fixed Point Theorem, will be proven in chapter 6. A short overview of this early development can be found in **Ref:Sambin Boolos**

It was proven in 1976 by Solovay that the modal logic now known as provability logic, is the logic of the provability predicate in Peano Arithmetics; i.e if for all interpretations of a formula α, if this interpretation was a theorem of Peano arithmetics, then the formula α was a theorem of provability logic. This also means

that provability logic can be seen as an axiomataxion of the proof predicate. Solovays result will be the main result in this project; it will be stated precisely and proven in Chapter 7.

After Solovay's article was published, the research focus of provability logic was to generalize Solovay's result to other fragments of arithmetics and if it did also hold for multi-modal provability logic and quantified provability logic. The results of these results will be commented on in the last part of chapter 7 and in chapter 8

2 Preliminary

In this section I will state a few results and definitions from my two project I have
written; one about modal logic and one about Gödel's incompleteness theorems.
These results will be given without proof. The proofs can be found in **Indsæt ref**.

The main points of this section will be the definition of the predicate $\Pr(\cdot)$ which
is constructed in the proof of Gödel's Incompleteness Theorems, and the definition
of the modal logic **GL** (The name comes from Gödel and Löb) and a few of the
properties of this modal logic. The main result of this project will be Solovay's
arithmetic completeness theorem, that simply put states that these two predicates
(from different mathematical systems) "behaves" in the same way.

2.1 Modal Logic

Modal logic will play an important rule in this project. The main point here, is
that provability can be seen as a modality. This will be swhon later on in the
project.

2.1.1 The language of modal logic

In this subsection we will define our language $\mathcal{L}_\Box$ of modal logic. We will have
start of with a set called Φ, which consists of propositional letter $p, q, \ldots$. We can
further define the primitive symbols of our modal language $\mathcal{L}_\Box$:

Definition 2.1 The following symbols are the primitive in our language $\mathcal{L}_\Box$

1. Every letter from the set Φ.

2. The logical constants $\bot$ (zero-ary) and $\rightarrow$ (binary)

3. The modal operator $\Box$ (unary).

$$\dashv$$

We can now define the well formed formulas of $\mathcal{L}_\Box$, or as we will call them for
the: *modal formulas.*

Definition 2.2 We define a *modal formula* recursively in the following way:

7

i Each $p \in \Phi$ is a modal formula

ii $\perp$ is a modal formula

iii If α and β are modal formulas then so is $\alpha \to \beta$.

iv If α is a modal formula then so is $\square \alpha$

v Nothing is a modal formula except as prescribed by (i)-(iv)

$\dashv$

Further we will define the connectives $\wedge, \neg, \vee, \leftrightarrow, \Diamond, \square^n, \Diamond^n$ and $\top$ in the usual way. We will read $\square \alpha$ as "α is provable. Normally in the alethic modal logic the $\square$ reads "α is necessarily true. Further the symbol $\perp$ stands for falsehood. We will read $\Diamond \alpha$ as "α" is consistent.

2.1.2 Semantics

In this section we will define the notation of truth for our modal logic. We will begin by defining a Hintikka frame and a Kripke model

Definition 2.3 (Hintikka frame) A *Hintikka frame* is a tuple $\mathcal{H} = \langle W, R \rangle$ where is W is non-empty set (we will call its members for nodes[1]) and where $R \subset W \times W$ is a relation that we will call the accessibility relation. We will use the notation wRv to denote that the note w sees the note v; i.e $(w, v) \in R$. $\dashv$

We do not at the given time give the relation R any properties. It could be reflexive, transitive or anti-symmetric.

Definition 2.4 (Kripke model) A *Kripke model* is a tuple $\mathcal{K} = \langle \mathcal{H}, \phi \rangle$ where $\mathcal{H}$ is a Hintikka frame and ϕ is a valuation function that to each proportional letter $p \in \Phi$ assigns a subset $\phi(p)$ of W. Formally:

$$\phi : \Phi \to \mathcal{P}(W)$$

$\dashv$

We can now define the notion of truth in a given Kripke model $\mathcal{K} = \langle \mathcal{H}, \phi \rangle$. If a modal formula α is true at a node w in a Kripke model $\mathcal{K} = \langle \mathcal{H}, \phi \rangle$ we will write:

$$\vDash_w^{\mathcal{K}} \alpha$$

This notation is taken from Lemmon 1977. Another notation instead of $\vDash_w^{\mathcal{K}} \alpha$ is $\mathcal{K}, w \vDash \alpha$.

---

[1] Normally the members of this set will be called worlds, but this interpretation do not make senses in provability logic

Definition 2.5 (Truth definition) We define the notion of *truth* in a Kripke modal $\mathcal{K} = \langle \mathcal{H}, \phi \rangle$ in the following way:

1. If α is propositional p then:

$$\vDash_w^{\mathcal{K}} \alpha \text{ iff } w \in \phi(p)$$

2. If α is $\bot$ then:

$$\vDash_w^{\mathcal{K}} \alpha \text{ iff never}$$

3. If α is $\beta \to \gamma$ then:

$$\vDash_w^{\mathcal{K}} \alpha \text{ iff if } \vDash_w^{\mathcal{K}} \beta \text{ then } \vDash_w^{\mathcal{K}} \gamma$$

4. if α is $\Box \beta$ then:

$$\vDash_w^{\mathcal{K}} \alpha \text{ iff for all } v \text{ such that } wRv \text{ we have } \vDash_v^{\mathcal{K}} \beta$$

$$\dashv$$

We will end this section with definitions of a *valid* and *satisfiable* formula.

Definition 2.6 For a given Hintikka frame $\mathcal{H} = \langle W, R \rangle$ we say that α is *valid* in $\mathcal{H}$ and write $\vDash^{\mathcal{H}} \alpha$ if and only if $\vDash_w^{\mathcal{K}} \alpha$ for all Kripke models on our frame $\mathcal{H}$ and all notes $w \in W$. Further we say that α is *satisfiable* in $\mathcal{H}$ if and only if $\vDash_w^{\mathcal{K}} \alpha$ for some Kripke model $\mathcal{K}$ on the frame $\mathcal{H}$ and some note $w \in W$.

α is called *valid* if and only if α is valid in all frames $\mathcal{H}$, if this is the case we simply write $\vDash \alpha$. α is called *satisfiable* if and only if α is satisfiable on all frames $\mathcal{H}$.

A formula α is called valid on a class of frames $\mathcal{C}$ if for all $\mathcal{H} \in \mathcal{C}$ we have that $\vDash^{\mathcal{H}} \alpha$. We write this as $\vdash^{\mathcal{C}} \alpha$.

A formula α is *valid* in a Kripke model $\mathcal{K} = \langle W, R, \phi \rangle$ if and only if $\vDash_w^{\mathcal{K}} \alpha$ for all notes $w \in W$. We write this as $\vDash^{\mathcal{K}} \alpha$

If a Kripke model $\mathcal{K}$ has a *minimal node* w_0, i.e a node such that for all $v \in W$ we have $w_0 R v$, then a modal formula α is called *true* in $\mathcal{K}$ if we have that $\vDash_{w_0}^{\mathcal{K}} \alpha$. $\dashv$

2.1.3 The modal logic GL

In this section we will define the notion of a modal logic and define the modal logic **GL**, which will be our base modal logic in this project.

Definition 2.7 A *modal logic* Λ is a set of modal formulas that contains all propositional tautologies, and is closed under *modus ponens* (MP) and uniform substitution. If $\alpha \in \Lambda$ we say that α is a theorem of Λ and write $\vdash_\Lambda \alpha$, else we write $\nvdash_\Lambda \alpha$.

We will also define the set $\Lambda_S = \{\alpha \vDash^S \alpha, \text{ for al structures } S \in S\}$. Where S is any class of frames. ⊣

We will further define when a given modal formula is deducible in a modal logic:

Definition 2.8 Let Λ be a modal logic, let $\beta_1, \ldots, \beta_n$ be modal formulas in Λ and let α be a modal formula. We say that α is *deducible* from $\beta_1, \ldots, \beta_n$ if $(\beta_1 \wedge \cdots \wedge \beta_n) \to \alpha$ is a tautology.

If $\Gamma \cup \{\alpha\}$ is a set of modal formulas, then α is *deducible* in Λ from Γ if $\vdash_\Lambda \alpha$ or if there are formulas $\beta_1, \ldots, \beta_n \in \Gamma$ such that:

$$\vdash_\Lambda (\beta_1 \wedge \cdots \wedge \beta_n) \to \alpha$$

In this case we write $\Gamma \vdash_\Lambda \alpha$ else we write $\Gamma \nvdash_\Lambda \alpha$ ⊣

We will now define what a *normal modal logic* is. We will later look at a modal logic that is not normal. But the modal logic **GL** is a normal one.

Definition 2.9 A modal logic Λ is called *normal* if it has the following axioms and deduction rules:

Tau All propositional tautologies.

K $\Box(p \to q) \to (\Box p \to \Box q)$

MP $p, \ p \to q \vdash_\Lambda q$ (*modus ponens*)

Nec $p \vdash_\Lambda \Box p$ (*necessitation*)

If Γ is a set of modal formulas we call the smallest normal logic contanting Γ the normal modal logic axiomatized by Γ. The normal modal logic axiomatized by empty set is called **K** and this is the smallest normal modal logic.[2] ⊣

A few standard results follows from these definitions:

Proposition 2.1 If Λ is a normal modal logic then:

1. If $\vdash_\Lambda \alpha \to \beta$ then $\vdash_\Lambda \Box\alpha \to \Box\beta$

2. $\vdash_\Lambda \Box(\alpha \wedge \beta) \leftrightarrow \Box\alpha \wedge \Box\beta$

3. $\vdash_\Lambda \Box(\alpha_1 \wedge \cdots \wedge \alpha_n) \leftrightarrow \Box\alpha_1 \wedge \cdots \wedge \Box\alpha_n$ for $n \geq 2$.

4. If $\vdash_\Lambda \beta_1 \wedge \cdots \wedge \beta_n \to \alpha$ then $\vdash_\Lambda \Box\beta_1 \wedge \cdots \wedge \beta_n \to \Box\alpha$, for $n \geq 0$.

---

[2]Here **K** stands for Kripke

It should further be noted that the axiom **K** is equivalent to the following formula:

$$\Box\alpha \wedge \Box(\alpha \to \beta) \to \beta$$

Smorynski uses this formula as an axiom instead of the axiom **K**. We can extend the logic **K** in the following way, to get the logic **GL** and the logic **4**.

Definition 2.10 **K4** is the modal logic extending **K** by adding the following axiom:

4 $\Box\alpha \to \Box\Box\alpha$

GL is the modal logic extending **K** by adding the two following axioms:

4 $\Box p \to \Box\Box p$

L $\Box(\Box p \to p) \to \Box p$

$\dashv$

Smorynski calls the modal logic **K4** for **BML** (Basic modal logic).

It can be shown that the axiom 4 is redundant. k It is now possible to define the notions of soundness, strong completeness and weak completeness.

Definition 2.11 Let S be a class of frames or models.

1. A normal modal logic Λ is sound with respect to S if $\Lambda \subseteq \Lambda_S$, i.e if $\vdash_\Lambda \alpha$ implies $\vDash^{\mathcal{S}} \alpha$ for all $\mathcal{S} \in S$.

2. A modal logic Λ is strongly complete with respect to S if for any set of formulas $\Gamma \cup \{\alpha\}$, if $\Gamma \vDash^{\mathcal{S}} \alpha$ then $\Gamma \vdash_\Lambda \alpha$ for all $\mathcal{S} \in S$ and it is weakly complete with respect to S if for any formula α if $\vDash^{\mathcal{S}} \alpha$ then $\vdash_\Lambda \alpha$ for all $\mathcal{S} \in S$.

$\dashv$

To show completeness results you will create a *canonical* model and then show that the given modal logic is complete with respect to this model. It can be shown that **K** is sound and strongly complete with respect to the class of all frames. A lot of different completeness results can be found in Lemmon 1977 and Blackburn 2002. Here we will just state a few of the results about **GL**.

Theorem 2.1 **GL** is not sound and strongly complete with respect to any class of frames.

There is another result concerning the completeness and soundness of **GL**. To state this we first need some definitions concerning relations:

Definition 2.12 A relation R on frame $\mathcal{H} = \langle W, R \rangle$ is said to be *transitive* if for all $w_1, w_2, w_3 \in W$, whenever $w_1 R w_2$ and $w_2 R w_3$ then $w_1 R w_3$.

The relation R is said to be *well-founded* on $\mathcal{H}$ if every non-empty subset $V \subseteq W$ has a minimal element with respect to R. In other words R is well-founded if there is no infinite sequence $\ldots R w_2 R w_1 R w_0$

Further the relation R is said to be *conversely well-founded* on $\mathcal{H}$ if the converse R^{-1} of R is well-founded; i.e if there is no infinite sequence such that $w_0 R w_1 R w_2 R \ldots$ ⊣

We can now state the following theor::

{thm:GLcomplete}

Theorem 2.2 **GL** is sound and weakly complete with respect to the class of transitive and conversely well-founded frames.

In chapter 5 we will show some further results about **GL** and in chapter 6 we will show a fixed point theorem about **GL**.

{prop:GL}

Proposition 2.2 $\vdash_{\mathbf{GL}} \Box(\alpha \leftrightarrow \beta) \to (\Box\alpha \leftrightarrow \Box\beta)$

Pris evt. nogle få deduktions former der vil blive brugt senere

2.2 Gödels Incompleteness Theorems

In this section we will state and sketch the proof of Gödels incompleteness theorems. In this sketch we will define a predicate $\Pr(\cdot)$ that says a given formula has a proof in arithemteics.

2.2.1 Primitive Recursive Functions

We will start of by defining a class of function that will both play a crucial role in the proof of Gödels Incompleteness Theorems, and in the rest of this project.

Definition 2.13 The class of primitive recursive functions is the smallest class closed under the following schemata:

  I. $S(x) = x + 1$ is primitive recursive.

  II. $Z(x) = 0$ is primitive recursive.

  III. $P_i^n(x_1, \ldots, x_n) = x_i$ is primitive recursive.

  IV. If $g, h_1, \ldots h_m$ are primitive recursive then so is

$$f(x_1, \ldots, x_n) = g(h_1(x_1, \ldots, x_n), \ldots, h_m(x_1, \ldots, x_n))$$

V. If g and h are primitive recursive and $n \geq 1$ then f is also primitive recursive where:

$$f(0, x_1, \ldots, x_n) = g(x_1, \ldots, x_n)$$
$$f(x_1 + 1, x_2, \ldots, x_n) = h(x_1, f(x_1, \ldots, x_n), x_2, \ldots, x_n)$$

⊣

We can also define relations as being primitive recursive:

Definition 2.14 A relation $R \subseteq \omega^n$ is primitive recursive if its chararestic function :

$$\chi_R(\vec{x}) = \begin{cases} 0 & \text{if } R(\vec{x}) \\ 1 & \text{if } R(\vec{x}) \end{cases}$$

⊣

So with these definitions we can show that some well known functions are primitive recursive.

Proposition 2.3 The following list of functions are all primitive recursive:

1.	$K_k^n(x_1, \ldots, x_n) = k$	Constant
2.	$A(x, y) = x + y$	Addition
3.	$M(x, y) = x \cdots y$	Multiplication
4.	$E(x, y) = x^y$	Exponentiation
5.	$pd(x) = \begin{cases} x - 1, & x > 0 \\ 0, & x = 0 \end{cases}$	Predecessor
6.	$x \dot{-} y = \begin{cases} x - y & x, \geq y \\ 0, & x < y \end{cases}$	Cut-off subtraction
7.	$sg(x) = \begin{cases} 0, & x = 0 \\ 1, & x > 0 \end{cases}$	Signum
8.	$\overline{sg}(x) = \begin{cases} 1, & x = 0 \\ 0, & x > 0 \end{cases}$	Signum complement
9.	$|x - y| = \begin{cases} x - y, & x \geq y \\ y - x, & x < y \end{cases}$	absolute value

2.2.2 PRA

In this section we will specify the rules and language of **PRA**. First of we will define the language $\mathcal{L}_{\textbf{PRA}}$ of **PRA**.

Definition 2.15 The language $\mathcal{L}_{\textbf{PRA}}$ consists of the following symbols:

$$
\begin{aligned}
\text{Variables} &: v_0, v_1, \ldots \\
\text{Constant} &: \overline{0} \\
\text{Function symbols} &: \overline{f} \text{ for each primitive recursive function } f \\
\text{Relation symbols} &: = \\
\text{propositional connectives:} &: \neg, \wedge, \vee, \rightarrow \\
\text{Quantifiers} &: \forall, \exists
\end{aligned}
$$

$\dashv$

We will now define the notions of terms and formulae of **PRA**. This part is mostly done to settle notations.

Definition 2.16   1. The set of *terms* of the langauge of **PRA** is defined inductively by:

   a) $\overline{0}$ is a term and each v_i is a term.

   b) If f is an n-ary function symbol and $t_1, \ldots t_n$ are terms then $\overline{f}t_1 \ldots t_n$ is a term.

2. The set of *formulae* of the language of **PRA** is defined inductively by:

   a) If t_1 and t_2 are terms then $= t_1 t_2$ is a formula.

   b) If F and G are formulae, so are $\neg F, \wedge FG, \vee FG$ and $\rightarrow FG$.

   c) If F is a formula and v is a variable, then $\exists v F$ and $\forall v F$ are also formulae.

$\dashv$

We use Polish notation so we do not have parentheses in our language. In practices we will use parentheses and infix notation. We will also need the definition of a *sentence*.

Definition 2.17 A formula F of **PRA** is called a sentence if it has no free variables; i.e if all variables v that occurs in F are bound. $\dashv$

Having defined the language of **PRA** we can now state the different axioms of **PRA**:

Definition 2.18 The axioms **PRA** are the following:

1. Propositional axioms

    a) $F \to (G \to F)$

    b) $(F \to (G \to H)) \to ((F \to G) \to (F \to H))$

    c) $F \land G \to F$

    d) $F \land G \to G$

    e) $F \to (G \to F \land G)$

    f) $F \to F \lor G$

    g) $G \to F \lor G$

    h) $(F \to H) \to ((G \to H) \to (F \lor G \to H))$

    i) $(F \to G) \to ((F \to \neg G) \to \neg F)$

    j) $\neg\neg F \to F$

2. Quantifier axioms

    a) $\forall v Fv \to Ft$

    b) $Ft \to \exists v Fv$

    Where t is substitutable for v in Fv in both cases.

3. Equality axioms

    a) $v_0 = v_0$

    b) $v_0 = v_1 \to v_1 = v_0$

    c) $v_0 = v_1 \land v_1 = v_2 \to v_0 = v_2$

    d) $v_i = w \to \bar{f}(v_1, \ldots, v_i, \ldots, v_n) = \bar{f}(v_1, \ldots, w, \ldots, v_n)$

    Where $1 \le i \le n$ and $\overline{f}$ is an n.ary function symbol.

4. Non-logical axioms

    a) Initial functions

        i. $\overline{Z}(v_0) = \overline{0}$

        ii. $\neg(\overline{0} = \overline{S}(v_0))$

        iii. $\overline{S}(v_0) = \overline{S}(v_1) \to v_0 = v_1$

        iv. $\overline{P}_i^n(v_1, \ldots, v_n) = v_1$ for $1 \le i \le n$

    b) Derived functions

  i. $\overline{f}(v_1, \ldots, v_n) = \overline{g}(\overline{h}_1(v_1, \ldots, v_n), \ldots, \overline{h}_m(v_1, \ldots v_n))$. Here f is defined by composition of $g, h_1, \ldots, h_m$

  ii. Let f be defined by primitive recursion form the primitive recursive function g and h, then the following to things holds:
$\overline{f}(\overline{0}, v_1, \ldots, v_n) = \overline{g}(v_1, \ldots, v_n)$ and
$\overline{f}(\overline{S}v_0, v_1, \ldots, v_n) = \overline{h}(\overline{f}(v_0 1, v_1, \ldots, v_n), v_0, v_1, \ldots, v_n)$

 c) Induction
 $F(\overline{0}) \wedge \forall v(\delta v \to F(\overline{S}v)) \to \forall v F(v)$ where $F(v)$ is

$$\exists v_n(\overline{f}(v, v_0, v_1, \ldots, v_n) = \overline{0})$$

$$\dashv$$

The induction axiom seems a bit strange at first. If we had allowed full induction; i.e induction on every formula, the system we would have defined would be know as **PA**; Peano Arithmetics. Having written down the axioms we will move on to the inference rules of **PRA**.

Definition 2.19 The inference rules of **PRA** are the following:

1. From $F, F \to G$, derive G. (modus ponens)

2. From $Fv \to G$ derive $\exists F \to G$, under the assumption that no v occurs free in G.

3. From $G \to Fv$ derive $G \to \forall v Fv$, under the assumption that no v occurs free in G.

A formal derivation in **PRA** is a sequence of formulas of **PRA** $F_0, F_1, \ldots, F_k$ such that each F_i is either an axiom of **PRA** or follows from two other formulas F_j, F_l where $j, l < i$ by one of the three inferences rules. $\dashv$

We will end this section with a theorem that states that **PRA** can compute the primitive recursive functions.

Theorem 2.3 Let f be an n-ary primitive recursive function and let $\overline{f}$ be the function symbol representing it in **PRA**. Then for all $n_1, \ldots, n_m, n \in \omega$ we have:

$$f(n_1, \ldots, n_m) = n \Rightarrow \textbf{PRA} \vdash \overline{f}(\overline{n_1}, \ldots, \overline{n_m}) = \overline{n}$$

That **PRA** can compute the primitive recursive functions makes it possible to encode the syntax of **PRA**. This will be explained in the next section.

2.2.3 Arithmetication of the syntax

In this section we will discus how each expression in the language F of **PRA** can be given a unique code-number $\ulcorner F \urcorner$ called the Gödel number. This makes it possible for **PRA** to express things about it self. For this encoding to work we will need the fundamental theorem of arithmetic that states that every natural number $a \geq 2$ has a unique representation:

$$a = p_{i_0}^{n_0} \cdots p_{i_k}^{n_k}$$

Where each p is a distinct prime and all the n_i are positive. If given a sequence $(j_0, \ldots j_t)$ we can coded it with a unique code in the following way:

$$c = 2^{j_0+1} 3^{j_1+1} \cdots p^{j_t+1}$$

So by this it is possible to give each formula of **PRA** a unique code. We will start of by listing the codes for some of our symbols of **PRA**:

1. $\ulcorner \overline{0} \urcorner$ is (0).

2. $\ulcorner = \urcorner$ is (1).

3. $\ulcorner \neg \urcorner$ is (2); $\ulcorner \wedge \urcorner$ is (3); $\ulcorner \vee \urcorner$ is (4) and $\ulcorner \rightarrow \urcorner$ is (5).

4. $\ulcorner \forall \urcorner$ is (6) and $\ulcorner \exists \urcorner$ is (7).

5. $\ulcorner v_i \urcorner$ is $(8, i)$.

These are the easy one to gives. The hard ones are the codes for the functions symbols. We will define the codes for these inductively as seen in the following table:

Function	Index
$Z(x) = 0$	$(9, 1, 1)$
$S(x) = x + 1$	$(9, 2, 1)$
$P_i^n(x_1, \ldots, x_n) = x_i$	$(9, 3, n, i)$
$f(\vec{x}) = g(h_1(\vec{x}), \ldots, h_m(\vec{x}))$	$(9, 4, n, m, (g^*, h_1^*, \ldots, , h_m^*))$
$f(0, x_1, \vec{x}) = g(\vec{x})$ $f(x+1, \vec{x}) = h(f(x, \vec{x}), x, \vec{x})$	$(9, 5, n+1, g^*, h^*)$

Table 2.1: The Codes for the Function Symbols

This encoding is primitive recursive so **PRA**, can do this encoding. But the proof of that is very tedious, so it is left out. A lot of different relations and

functions can be shown to be primitive recursive, one of the important ones is the function $subst(x; y, z)$ which substitutes z for y in the formula x. With this it is possible to show primitive recursively define our axioms of **PRA**. This means that **PRA** is capable of identifying its own axioms. Further it can also identify that if a given sequence of formulas is a proof of another given formula; i.e the relation that says "y codes a derivation of the formula with code x". We shorten this as $\mathrm{Prov}(x, y)$ and we further define the non primitive recursive relation "x codes a provable formula" as: $\mathrm{Pr}(x) \leftrightarrow \exists y(\mathrm{Prov}(y, x))$

2.2.4 The proof predicate and the theorems

The relation $\mathrm{Pr}(x)$ has the following properties called Löbs derivability conditions:

D1 $\mathbf{PRA} \vdash F \Rightarrow \vdash \mathrm{Pr}(\ulcorner F \urcorner)$

D2 $\mathbf{PRA} \vdash \mathrm{Pr}(\ulcorner F \to G \urcorner) \to (\mathrm{Pr}(\ulcorner F \urcorner) \to \mathrm{Pr}(\ulcorner G \urcorner))$

D3 $\mathbf{PRA} \vdash \mathrm{Pr}(\ulcorner F \urcorner) \to \mathrm{Pr}(\ulcorner \mathrm{Pr}(\ulcorner F \urcorner) \urcorner)$

it is also clear that $\neg \mathrm{Pr}(\bot)$, where $\bot$ is some false statement expresses consistence. We will denote this by Con. We can further with the use of the *subst* function prove the following important lemma:

Lemma 2.1 (The fixed point lemma) Given any formula G where the only free variable is v, we can find a sentence F such that:

$$\mathbf{PRA} \vdash F \leftrightarrow G(\ulcorner F \urcorner)$$

This lemma makes it possible for us to show the first incompleteness theorem:

Theorem 2.4 (The First Incompleteness Theorem) The predicate $\mathrm{Pr}(\cdot)$ have the following properties for all formulas G:

1. $\mathbf{PRA} \vdash G \Rightarrow \vdash \mathrm{Pr}(\ulcorner G \urcorner)$

2. $\mathbf{PRA} \vdash \mathrm{Pr}(\ulcorner G \urcorner) \Rightarrow \vdash G$

If we let $\mathbf{PRA} \vdash F \leftrightarrow \neg \mathrm{Pr}(\ulcorner F \urcorner)$, we then have:

1. $\mathbf{PRA} \nvdash F$

2. $\mathbf{PRA} \nvdash \neg F$

I.e we have a sentence where neither it or its negation can be proven. So our system is incomplete.

Since $\Pr(\cdot)$ fullfills the derivability conditions the second theorem can also be proven.

Theorem 2.5 (The Second Incompleteness Theorem) Under the assumption that **PRA** is consistent we have that **PRA** $\nvdash \mathrm{Con}$

The main goal for the rest of this project is now to prove that the $\square$ in **GL** "behaves" in the same way as the $\Pr(\cdot)$ predicate from arithmetics. How to should be understood will be explained latter on. To prove this theorem we will first need a main result from Recursion Theory called the recursion theorem.

We will need one more result about the proof predicate in the project. It is called the formalized Löb's theorem, and this theorem together with the derivability conditions tells the full story about the predicate $\Pr(\cdot)$

Theorem 2.6 (Formalized Löb's Theorem) Let F be any sentence of **PRA**. Then:

$$\mathbf{PRA} \vdash \Pr(\ulcorner \Pr(\ulcorner F \urcorner) \to F \urcorner) \to \Pr(\ulcorner F \urcorner)$$

We will in a later section need the following lemma:

{lem:Prov}

Lemma 2.2 Let $\overline{f}$ be an n-ary primitive recursive function symbol. There is a function g depending on f, such that:

$$\mathbf{PRA} \vdash \overline{f}v_0 \ldots v_{n-1} = v \to \mathrm{Prov}(\overline{g}v_0 \ldots v_{n-1}, \ulcorner f\dot{v}_0 \ldots \dot{v}_{n-1} = \dot{v}_n \urcorner)$$

The Formalized Löb's Theorem and the derivability conditions can be shown to hold for a wide range of arithmetical systems. A overview over this subject will be given in chapter 4. If we write $\vdash F$ instead of **PRA** $\vdash F$ it means we have not specified the arithmetical system we are looking at.

If we set the properties of $\Pr(\cdot)$ up next to the properties of the $\square$-operator of **GL**, we get the following table:

$\vdash_{\mathbf{GL}} \alpha \Rightarrow \vdash_{\mathbf{GL}} \square\alpha$	$\vdash F \Rightarrow \vdash \Pr(\ulcorner F \urcorner)$
$\vdash_{\mathbf{GL}} \square(\alpha \to \beta) \to (\square\alpha \to \square\beta)$	$\vdash \Pr(\ulcorner F \to G \urcorner) \to (\Pr(\ulcorner F \urcorner) \to \Pr(\ulcorner G \urcorner))$
$\vdash_{\mathbf{GL}} \square\alpha \to \square\square\alpha$	$\vdash \Pr(\ulcorner F \urcorner) \to \Pr(\ulcorner \Pr(\ulcorner F \urcorner) \urcorner)$
$\vdash_{\mathbf{GL}} \square(\square\alpha \to \alpha) \to \square\alpha$	$\vdash \Pr(\ulcorner \Pr(\ulcorner F \urcorner) \to F \urcorner) \to \Pr(\ulcorner F \urcorner)$

Table 2.2: The properties of $\square$ and the predicate $\Pr(\cdot)$

It is clear from this table that the predicate $\Pr(\cdot)$ and the $\square$-operator of **GL** have a lot of the same properties in common. Solovay's completeness theorems shows that the modal logic **GL** in some way axiomatize the proof predicate of a wide range of different arithmetical systems.

3 Recursion Theory

We will begin this section with define two classes of functions; the *Partial Recursive Functions* and the *Turing Computable functions*. These two classes of functions gives rise to the same class of functions The idea behind these two classes of functions is to define what we intuitively mean with a computable function. The proofs in this section will be rather informal. The goal of this section will be to state and prove Kleene's recursion theorem, which will play a crucial role in our proof of Solovay's two completeness theorems. Further there will also be a few results and comments on the so called arithmetical hierarchy, which will make it possible for us to generalize Solovay's theorems.

The topic I have chosen to call recursion theory is today often know as computability theory. Robert Soares have stated some arguments for why this name is better suited for the discipline than the name recursion theory in his book Soare 2016.

This sections will follow Soare 1987, unless stated otherwise.

3.1 Partial Recursive Functions and Recursive Functions

The class of partial recursive functions is an enlargement of the primitive recursive functions. The class of primitive recursive functions capture a lot of the function we intuitively sees as computable. It does not contain any function that we would say was incomputable.

But the primitive recursive functions do not include all intuitively computable functions. For example the following function, called the Ackermann function, that is clearly computable is not in the class of primitive recursive functions:

$$Ack(0, n) = n + 1$$
$$Ack(m + 1, 0) = A(m, 1)$$
$$Ack(m + 1, n + 1) = A(m, A(m + 1, n))$$

This function grows *to fast* to be a primitive recursive function. A proof of this fact can be found in **Find ref**.

So we will need to expand our class of functions, if we want to *capture* all intuitively computable functions. We will expand them in the following way:

Definition 3.1 The class of *partial recursive* (from now on some times called (p.r) functions is the least class closed under schemata I through V from the definition of primitive recursive functions and the following VI schema .

VI. If $\theta(x_1, \ldots, x_n, y)$ is a partial recursive function of $n + 1$ variables and

$$\psi(x_1, \ldots, x_n) = \mu y[\theta(x_1, \ldots, x_n, y) \downarrow = 0$$
$$\wedge \forall z \le y[\theta(x_1, \ldots, x_n, z) \downarrow]$$

Then ψ is a partial recursive function of n variables

A partial recursive function that is total is called a total recursive function; abbreviated to recursive function. $\dashv$

This is one way in which one can define what the computable functions are. In the next section we will come with another definition of a type of functions, and it will be shown that these leads to the same class of functions.

We will end this section with the following definition:

Definition 3.2 A relation $R \subset \omega^n$ where $n \ge 1$, is recursive (primtive recursive) if its characteristic function χ_R is recursive (primitive recursive). The case where $n = 1$ is the case where R is a set $A \subset \omega$ so we also have the definition of a set being recursive. $\dashv$

3.2 Turing Computable Functions

Another way to describe the intuitively computable functions is via a Turing machine.

Definition 3.3 A *Turing machine M* consists of a two-way infinite tape that is dived into different cells and a finite set of internal states $Q = \{q_0, \ldots, g_n\}$, $n \ge 1$. Each cell is either blank: B or has value 1. The following three things can happen in a single step:

1. Change form one state to another.

2. Change the scanned symbol s to another symbol $s' \in S = \{1, B\}$

3. Move the reading head one cell to the right R or the left L.

The operation of M is controlled by a partial map:

$$\delta : Q \times S \to Q \times S \times \{R, L\}$$

Which may not be defined for all arguments. ⊣

The situation can be seen in the following figure:
Figure 3.1: A Turing Machine

The way to understand this definition is the following: if $(q, s, q', s', X) \in \delta$ it means that the machine M is in stage q where it scans symbol s then changes to state q' and replaces s by s'. Lastly it moves to the right if $X = R$ and the left if $X = L$. The map δ is called a Turing program if it can be views as a finite set of quintuples. If the input integer is x then it will be represented by a string of $x + 1$ consecutive $1's$, where all other cells are blank.

Further the machine M start in the state q_1 scanning the left-most cell that contains a 1. The machine stops if it reaches the halting state q_0, and it will then output the number y which is the total number of 1's on the tape in the this state. If M with input x halts and outputs y we say that M computes the partial function $\psi(x) = y$

The conditi [Indfør noget mere tekst her]on a is determined by:

1. The current state q_i

2. The symbol s_0 that is being scanned.

3. The symbols on the tape to the right of s_0 up to the last 1. Denote this sequence by $s_1, s_2, \ldots s_n$

4. The symbols on the tape to the left of s_0 op to the first 1. Denote this sequence by $s_{-1}, s_{-2}, \ldots s_{-m}$

This is called the configuration of the machine and we can write it as follows:

$$s_{-m} \cdots s_{-1} q_0 s_0 s_1 \cdots c_n$$

Definition 3.4 A Turing computation according to to the Turing program P with input x is a sequence of configurations $c_0, c_1, \ldots, c_n$ such that c_0 represent the machine in the halting state q_0, and the transition $c_i \to c_{i+1}$ for all $i < n$ is giving by the Turing program P. ⊣

Proposition 3.1 Each Turing program P_e can be assigned a Gödel number e.

Proof. We will use the fact that each $x \in \omega$ has a unique prime decomposition:

$$x = p_0^{x_0} \cdots p_n^{x_n} \cdots$$

We can assign a number to each quintuple $(q_{i,j}, q_k, s_l, r_m)$ in a Turing program P in the following way[Omformuler denne sætning]:

$$p_0^{1+i} p_1^{1+j} p_2^{1+k} p_3^{1+l} p_4^{1+m}$$

Where we have that $r_0 = R$ and $r_1 = L$. Since the prime decomposition is unique, each different state of the program has a unique code. Each Turing is a sequence of different states and we can thus for an arbitrary Turing program P_e we let $e_0, \ldots e_n$ denote the Gödel number of each different state and set:

$$e = p_0^{e_0} \cdots p_n^{e_n}$$

Thus each Turing program P_e has a unique Gödel number e. ⊣

Since each Turing program has a unique code we can list them and be able to find any program P_e by its code e. This gives the following definition:

Definition 3.5 The P_e be the Turing program with Gödel number e in the list and let $a_e^{(n)}$ be the function of n variables computed by P_e. Further let a_e abbreviate $a_e^{(1)}$. ⊣

3.3 The *s-m-n*-Theorem

It can be proven that the two classes of functions; partial recursive and Turing computable functions gives rise to the same class of partial functions. This can

be seen as evidence for *Church's Thesis* which states that this class of functions coincide with the function that we see as intuitively computable. In the rest of this project we will assume that the Church's Thesis is true.

We will being by proving the padding lemma, which states that each partial function φ_x has an infitine amount of indices.

Lemma 3.1 (The Padding Lemma) Each partial recursive function φ_i has $\aleph_0$ indicies, and for each x we can *effectively* find an infinite set A_x of indices for the same partial function.

Proof. For any program P_x that have internal states: $\{q_0, \ldots, q_n\}$ we can add extra instructions $q_{n+1}B\ R, q_{n+2}B\ R, \ldots$ such that we get a new program for the same computation. ⊣

The following theorem will show that each Turing computable function is in fact partial recursive. The converse also holds and the proof of this fact can be found in Klenne 1952

{thm:Normalform}

Theorem 3.1 (The Normal Form Theorem) There exist a predicate $T(e, x, y)$ and a function $U(y)$ that are primitive recursive such that:

$$\varphi_e(x) = U(\mu y T(e, x, y))$$

Proof. We showing that the predicate $T(e, x, y)$ exists and is primitive recursive. This predicate informally states that y is the code of Turing program P_e with input x. For each possible configuration c, we can assign a code:

$$\#(c) = 2^{1+i}3^{1+\#(s_0)}5^r7^l$$

Where $\#(s) = 0$ if $s = B$ and is equal to 1 otherwise, $r = \prod_{j \geq 1} p_j^{\#(s_j)}$ and $l = \prod_{j \leq -1} p_j^{\#(s_j)}$ We can now define the code of a Turing computation $c_0, c_1, \ldots c_n$ according to P_e to be:

$$y = 2^e \prod_{i \leq n} p_{i+1}^{\#(s_i)}$$

We can now define $T(e, x, y)$ to be [Læs i Kleene] Having defined the predicate T we can check if it holds. By proposition 2.1 we can "recover" the program P_e form e. Then we can recover the computation $c_0, c_1, \ldots c_n$ form y if y codes such a thing. We can now check if $c_0, c_1, \ldots, c_n$ is a computation according to P_e with x as the input in the first configuration c_0. If this is true, then $U(y)$ just outputs the number of 1's in the final configuration c_n. [Læs mere i Klenne] ⊣

This theorem also gives us that each partial recursive function can be created by two primitive recursive functions, with a single application of the μ-operator.

{thm:Emu}

Theorem 3.2 (Enumeration Theorem) There is a partial recursive function of 2 variables $\varphi_z^{(2)}(e,x)$ such that $\varphi_z^{(2)}(e,x) = \varphi_e(x)$.

Proof. By Theorem 3.1 we will define $\varphi_z^{(2)}(e,x) = U(\mu y T(e,x,y)) = \varphi_e(x)$ $\dashv$

We will need the following notation in the next proof:

Definition 3.6 Set $\langle x, y \rangle$ to be the image of (x,y) under the injective recursive pairing function:

$$\frac{1}{2}(x^2 + 2xy + y^2 + 3x + y)$$

This function is from $\omega \times \omega$ onto ω.[Måske let mere?] $\dashv$

Theorem 3.3 (s-m-n theorem) For every $m, n \geq 1$ there exists an injective recursive function s_n^m of $m+1$ variable such that for all $x, y_1, \ldots, y_m$

$$\varphi_{s_n^m(x,y_1,\ldots,y_m)}^{(n)} = \lambda z_1, \ldots z_n [\varphi_x^{(m+n)}(y_1, \ldots, y_m, z_1, \ldots, z_n)]$$

Proof. I will follow Soare and only proof the case where $m = n = 1$. I.e the case where we have to proof:

$$a_{s_1^1(x,y)}(z) = [a_x^2(y,z)]$$

Let x and y på given. Then $s_1^1(x,y)$ can be described as follows:

1. Let P_x the Turing program with code x.

2. Change P_x into another Turing program $P_{x'}$ such that: $P_{x'}$ writes $y + 1$ ”1” left of the input, such that there is a B between these 1 and the other input. Further i places the head to the left of the new input and proceeds to *run* P_x.

3. outputs x'

it is clear that $P_{x'}$ on input z compute the same as p_e would on input (x,y); i.e $\varphi_{x'} = \varphi_x^{(2)}(y,z)$. Further we have that $x' = s_s^1(x,y)$ By Church's Thesis the function $s = s_1^1$ is recursive, since it can be computed effectively. If it is not injective it can be replaced by a injective recursive function s' such that $\varphi_{s(x,y)} = \varphi_{s'(x,y)}$ by using the padding lemma and by defining $s'(x,y)$ in increasing order of $\langle x, y \rangle$. $\dashv$

A full proof of this statement can be found in Kleene. The $s - m - n$ theorem plays a crucial role in both the proof and the use of the recursion theorem. **Skriv noget om intuiton**. Therefore we will use the $s - m - n$ theorem to prove the following proposition:

Proposition 3.2 There is a recursive function g of two variables such that for all x, y:

$$\varphi_{g(x,y)} = \varphi_x \varphi_y$$

Proof. By Church's Thesis it is clear that $\eta = \varphi_x \varphi_y$ is a partial recursive function since it is the product of two partial recursive functions.

To end the proof we must show that we can find Gödel number for η in an uniform effective way from x and y as x and y vary. We will start of by defining:

$$\theta(x, y, z) = \varphi_x(\varphi_y(z)) = \varphi_{x_1}(x, \varphi_{x_1}(y, z))$$

Where φ_{x_1} is the function $\varphi_z^{(2)}$ from Theorem 3.2. By the church thesis this function is partial recursive and has an index e. So by applying the $s - m - n$ Theorem we get:

$$\varphi_x \varphi_y = \lambda z [\varphi_e(x, y, z)] = \varphi_{s_1^2(e,x,y)}$$

And thus $s_1^2(e, x, y)$ is our g (i.e $\lambda xy[s_1^2)e, x, y)]$. $\quad\dashv$

3.4 Recursively Enumerable sets and the Graph of a function

In this section we will introduce the two concepts *recursive enumerable* sets and the *graph* of a function. We will further show that there is connection between these two concepts.

Definition 3.7 A set A is *recursively enumerable* (r.e.) if A is the domain of some primitive recursive function. Further we define the following two sets:

1. We let the eth r.e set be denoted by:

$$E_e = \text{dom } (\varphi_e) = \{x : f(x) \downarrow\} = \{x : \exists y T(e, x, y)\}$$

2.

$$E_{e,s} = \text{dom}(\varphi_{e,s})$$

$\dashv$

A set can be recursively enumerable without being recursive, which the following two propositions shows:

Proposition 3.3 Let $K = \{x : \varphi_x(x) \text{ converges}\} = \{x : x \in E_x\}$, then K is r.e.

Proof. We have that K is the domain of the following primitive recursive function:

$$\psi(x) = \begin{cases} x & \text{if } \varphi_x(x) \text{ converges} \\ \text{undefined} & \text{otherwise.} \end{cases}$$

This function is primitive recursive by Church Thesis, since $\psi(x)$ can be computed by program P_x on input x, which outputs x only if $\varphi_x(x)$ converges. $\dashv$

Proposition 3.4 K is not recursive

Proof. If K where recursive we would that it had a recursive characteristic function K_χ, and thus the following would be recursive:

$$f(x) = \begin{cases} \varphi_x(x) + 1 & \text{if } x \in K \\ 0 & \text{if } x \notin K \end{cases}$$

But we this f can not be recursive since for all x we have $f \neq \varphi_x$. $\dashv$

Forklar kort meningen med dette.

Next goal is to show that the definition of a r.e sets is equivalent to the definition that there is an algorithm that enumerates the members of it. We will further also show that the definition of a r.e set is equivalent to the set being Σ_1, which is a concepts that will play a bigger role later on in this project.

Definition 3.8 A set A is the *projection* of some relation $R \subseteq \omega \times \omega$ if $A = \{x : \exists y : R(x, y)\}$. We further say that a set A is in Σ_1 form, if A is the projection of some recursive relation $R \subseteq \omega \times \omega$. $\dashv$

We can now show the following theorem:

Theorem 3.4 A set A is r.e iff A is Σ_1.

Proof. ($\Rightarrow$) Since A is r.e we have that $A = W_e = \text{dom} f_e$ for some e. This means that:

$$x \in W_e \Leftrightarrow \exists s(x \in W_{e,s}) \Leftrightarrow \exists s(T(e, x, s))$$

Since the relation T is primitive recursive and we have that the set A is the projection a recursive relation.

($\Leftarrow$) Let $A = \{x : \exists y(Rx, y)\}$ where R is recursive. We then have that $A = \text{dom} f$ where $f(x) = \mu y(R(x, y))$ and thus A is r.e $\dashv$

Skriv noget metatekst

:RecSigma}

Theorem 3.5 If there is a recursive relation $R \subseteq \omega^{n+1}$ and if we have the following set:

$$A = \{x | \exists y_1 \ldots \exists y_n R(x, y_1, \ldots, y_n)\}$$

Then the set A is Σ_1

Proof. We will start of by defining the relation $S \subseteq \omega^2$ as follows:

$$S(x, z) \Leftrightarrow R(x, (z)_1, \ldots, (z)_n)$$

Where we have the following prime decomposition of z:

$$z = p_1^{(z)_1} \cdots p_k^{(z)_k}$$

Then the following equivalences holds:

$$\exists z S(x, z) \Leftrightarrow \exists z R(x, (z)_1, \ldots (z)_n)$$
$$\Leftrightarrow \exists y_1 \cdots \exists y_n R(x, y_1, \ldots, y_n)$$

And thus the set A is clearly Σ_1. $\quad\dashv$

From this theorem we can easily get the following corollary:

Corollary 3.1 The projection of an r.e relation is r.e

The next definition will also play a role in our proof of Solovay's completeness theorems.

Definition 3.9 The graph of a (partial) function φ is the relation:

$$(x, y) \in \text{ graph}\varphi \Leftrightarrow f(x) = y$$

We will from now on denote the graph of a function $\varphi(x_1, \ldots, x_n) = y$ by
$\tau x_1, \ldots, x_n y$ $\quad\dashv$

Theorem 3.6 If $R \subseteq \omega^2$ is an r.e relation, then there is a p.r function sel called the selector function for R such that:

$$\text{sel}(x) \text{ is defined } \Leftrightarrow \exists y(R(x, y))$$

and if this is the case we have that $(x, f(x)) \in R$

Proof. Since R is r.e it is Σ_1. This means that there is a recursive relation S such that $R(x, y)$ holds iff $\exists z(S(x, y, z))$. Thus we can define the following primitive recursive function:

$$g(x) = \mu u(S(x, (u)_1, (u)_2))$$

And now we put $f(x) = (g(x))_1$ ⊣

It will be the following theorem we will use in our proof later on.

Theorem 3.7 A partial function φ is partial recursive iff its graph is recursive enumerable.

Proof. ($\Rightarrow$) The graph of φ_e is r.e by theorem 3.5 and the definition of a graph.

($\Leftarrow$) Since the graph of φ is assumed to be r.e we can conclude that φ is its own primitive recursive selector function. This is that $R = \text{graph}\varphi$ can only have φ as its selector function. [Whyyy?] ⊣

3.5 The Recursion Theorem

In this section we will state and prove the recursion theorem. It will be crucial in the next [chapter?], since we will need it to define a function.

Theorem 3.8 (The Recursion Theorem) For every recursive function f there exists a fixed point n such that $\varphi_n = \varphi_{f(x)}$

Proof. We will start of be defining the following *diagonal* function $d(u)$ as:

{eq:du}
$$\varphi_{d(u)}(z) = \begin{cases} \varphi_{\varphi_u(u)}(z) & \text{if } \varphi_u(u) \text{ converges} \\ \text{undefined} & \text{else} \end{cases} \tag{3.1}$$

By the $s-m-n$ theorem we have that the function d is injective and total. Further it is clearly seen that d is independent of f.

Given an arbitrary f we will choose an index v such that:

{eq:fd}
$$\varphi_v = f \circ d \tag{3.2}$$

Now set $n = d(v)$. We will show that this is a fixed point for the function f. Since f is total we also have that $f \circ d$ is total. This means that $\varphi_v(v)$ converges and that $\varphi_{d(v)} = \varphi_{\varphi_v(v)}$. Thus we have:

$$\varphi_n = \varphi_{d(v)} = \varphi_{\varphi_v(v)} = \varphi_{f \circ d(v)} = \varphi_{f(n)}$$

The second equality sign follows from 3.1 and the third follows from 3.2. ⊣

Following [Owens, find ref], the argument in the proof can be seen as a digitalization argument that fails. Commonly when we apply a digitalization argument, we have a class of sequences, with terms from an set A, that we arranges as the rows in a square matrix. We then have a map $h : A \to A$ that induces a operation

h^* on the set of sequences such that if $\langle s(i), i \in I \rangle$ is a sequences in our matrix then

$$h^*(\langle s(i), i \in I \rangle) = \langle h(s(i)), i \in I \rangle$$

After having defined this map we will use it on the sequences that consists of the elements of the diagonal of the matrix and show that the resulting sequences is not one of the original sequences.

The digitalization argument "fails" in our case, since the sequences of the diagonal is already already one of the rows and thus the image h^* of this sequences will also be one of the rows; i.e the h has a fixed point.

The start of the proof can be seen as the following lemma:

Lemma 3.2 There is a diaognal function $d(u)$ such that:

$$\varphi_{d(u)}(z) = \begin{cases} \varphi_{\varphi_u(u)}(z) & \text{if } \varphi_u(u) \text{ converges} \\ \text{undefined} & \text{else} \end{cases} \tag{3.3}$$

Most of the times where one uses the Recursion Theorem, one actually uses this lemma to construct the given function.

3.5.1 Application of the Recursion Theorem

The recursion theorem is a "powerful" tool. It enables us to define a partial recursive function, which uses its own index as part of its definition. This The recursion theorem overrides this "self-reference" because we are using the $s-m-n$ theorem to define a function $f(x)$ and $\varphi_{f(x)}(z) = (\ldots, x \ldots)$ and then taking a fixed point: $\varphi_n = \varphi_{f(n)}$. When we are making constructions like this the only thing we cannot do is use specific properties of the function φ_n. We will use the theorem in this way in our proof of Solovay's Completeness Theorems to define a function with help of the functions own Gödel number; and the recursion theorem makes this a viable tactic.

The following examples will show a few uses of this theorem.

Example 3.1 We will show that there is a n such that:

$$W_n = \{n\}$$

We start of by using the $s-m-n$ theorem to define $W_{f(x)} = \{x\}$ then by the recursion theorem we can choose n such that we have:

$$W_n = W_{f(n)} = \{n\}$$

$\dashv$

The next example will be a application of the Recursion Theorem that is in the same vein as the one we will use when we have to prove Solovay's completeness theorems.

Example 3.2 Let $\psi : \omega^2 \to \omega$ and $\theta : \omega^3 \to \omega$ be recursive functions and define the function $\varphi : \omega^2 \to \omega$ by:

$$\varphi(0, y) = \psi(y)$$
$$\varphi(x + 1, y) = \theta(\varphi(x, y), x, y)$$

We will now show that φ is recursive by using the recursion theorem.

Let $\phi_0 v_0 v_1$ be an arbitrary graph and let $\phi_1 v_0 v_1$ be the graph of ψ and $\chi v_0 v_1 v_2$ be the graph of θ. We will now look at the following formula:

$$\Phi(\phi_0) : \ (v_0 = \overline{0} \wedge \phi_1 v_0 v_1) \vee (v_0 > \overline{0} \wedge \exists v(\phi_0(v_+ - 1, v) \wedge \chi v v_0 v_1))$$

We can see $\ulcorner \Phi(\phi_0) \urcorner$ as a primitive recursive function of $\ulcorner \phi_0 \urcorner$. I.e we have:

$$\ulcorner \Phi(\phi_0) \urcorner = \eta(\ulcorner \phi_0 \urcorner)$$

We can now use the Recursion Theorem to chose a n such that we have: $\varphi_{\eta(n)}^{(2)} = \varphi_n^{(2)}$ and for $varphi = \varphi_n^{(2)}$ we have:

$$\varphi(x, y) = z \leftrightarrow (x = 0 \wedge \psi(y) = z = \vee (x > 0 \wedge \theta(\varphi(x - 1, y), x, y) = z)$$

I.e φ does exactly what we want it to do. WE just need to define φ and this can be done by a Σ_1 induction. $\dashv$

3.6 The Arithmetical Hierarchy

In this section we will introduce the so called arithmetical hierarchy. Parts of it has already be defined; i.e the sets Σ_1. In the arithmetical hierarchy, we can classify sets with respect to their quantifier complexity in their syntactical definition.

In the next chapter about the fragments of arithmetics, we will use the arithmetical hierarchy as a tool to detemine the amount of induction we will have in a given fragment.

The goal of this section is to introduce the arithmetical hierarchy and prove some results about it. The most of these results might not be used going forward.

Definition 3.10 We define the sets Σ_n and Π_n in the following way:

1. A set A is in Σ_0 (Π_0) if and only if A is recursive.

2. For $n \geq 1$ the set A is in Σ_n if there is a recursive relation $R(x, y_1, \ldots, y_n)$ such that:
$$x \in A \text{ iff } \exists y_1 \forall y_2 \exists y_3 \cdots Q y_n R(x, y_1, \ldots, y_n)$$

Here Q is $\exists$ if n is odd and Q is $\forall$ if n is even. We define A being in Π_n likewise. A is in Π_n if:

$$x \in A \text{ iff } \forall y_1 \exists y_2 \forall y_3 \cdots Q y_n R(x, y_1, \ldots, y_n)$$

3. A is in Δ_n if $A \in \Sigma_n \cap \Pi_n$

We further say that a formula φ is Σ_n (Π_n) if it is Σ_n (Π_n) as a relation of the variables that are free in it. $\dashv$

In the rest of this project we will mostly look at formulas that are either Σ_n or Π_n and not sets, that have this property.

We can show a few properties of these sets.

Proposition 3.5   1. $A \in \Sigma_n \Leftrightarrow \overline{A} \in \Pi_n$

2. $A \in \Sigma_n(\Pi_n) \Rightarrow (\forall m > n)(A \in \Sigma_m \cap \Pi_m)$

3. $A, B \in \Sigma_n(\Pi_n) \Rightarrow A \cup B, A \cap B \in \Sigma_n(\Pi_n)$

4. $(R \in \Sigma_n \wedge n > 0 \wedge A = \{x : \exists y R(x, y)\}) \Rightarrow A \in \Sigma_n$

5. $(B \leq_m A \wedge A \in \Sigma_n) \Rightarrow B \in \Sigma_n$

6. If $R \in \Sigma_n(\Pi_n)$ and A and B are defined by:

$$\langle x, y \rangle \in A \Leftrightarrow \forall z < y R(x, y, z)$$

and
$$\langle x, y \rangle \in B \Leftrightarrow \exists z < y R(x, y, z)$$

Then we have $A, B \in \Sigma_n(\Pi_n)$

Proof.   1. If we have that:

$$A = \{x : \exists y_1 \forall y_2 \cdots R(x, y_1, \ldots)\}$$

Then we have:
$$\overline{A} = \{x : \forall y_1 \exists y_2 \cdots \neg R(x, y_1, \ldots)\}$$

Which is clearly Π_n.

2. If for example $A = \{x : \exists y_1 \forall y_2 R(x, y_1, y_2)\}$, then we can make the following reformulation of A:

$$A = \{x : \exists y_1 \forall y_2 \exists y_3 (Rx, y_1, y_2) \wedge y_3 = y_3)\}$$

This kind of reformulation can be done for any set in Σ_n (Π_n)

3. Let the following to sets be defined:

$$A = \{x : \exists y_1 \forall y_2 \cdots R(x, y_1, y_2, \ldots)\}$$

$$B = \{x : \exists z_1 \forall z_2 \cdots S(x, z_1, z_2, \ldots)\}$$

Then we have:

$$
\begin{aligned}
x \in A \cup B &\Leftrightarrow \exists y_1 \forall y_2 \cdots R(x, y_1, y_2, \ldots) \vee \exists z_1 \forall y_2 \cdots S(x, z_1, z_2 \ldots) \\
&\Leftrightarrow \exists y_1 \exists z_1 \forall y_2 \forall z_2 \cdots (R(x, y_1, y_2, \ldots) \vee S(x, z_1, z_2, \ldots)) \\
&\Leftrightarrow \exists u_1 \forall u_2 \cdots (R, (u_1)_0, (u_2)_0, \ldots) \vee S(x, (u_1)_1, (u_2)_1, \ldots))
\end{aligned}
$$

Which is clearly Σ_n. The same argument can be made for $A \cap B$ and for Π_n sets.

4. This follows by quantifier contraction, in the same way as (3)

5. Let
$$A = \{x : \exists y_1 \forall y_2 \cdots R(x, y_1, y_2, \ldots)\}$$

And let $B \leq_m A$ via the function f. Then we have:

$$B = \{x : \exists y_1 \forall y_2 \cdots R(f(x), y_1, y_2, \ldots)\}$$

6. We will prove this by induction on n.

   Base case: Let $n = 0$. Then A and B are clearly recursive.

   Induction step: Now assume that $n > 0$ and suppose that $R \in \Sigma_n$. Our induction hypothesis says that (6) is true for all $m < n$. Then by (4) we have that $B \in \Sigma_n$. Further we have $S \in \Pi_{n+1}$ such that the following holds:

$$
\begin{aligned}
\langle x, y \rangle \in A &\Leftrightarrow (\forall z < y) R(x, y, z) \\
&\Leftrightarrow (\forall z < y) \exists u S(x, y, z, u) \\
&\Leftrightarrow \exists \sigma (\forall z < y) S(x, y, z, \sigma(z))
\end{aligned}
$$

   WE have that σ range is in $\omega^{<\omega}$. By the indction hypothesis we have that $(\forall z < y) S \Pi_{n+1}$ but by the above deduction we must then have that $A \in \Sigma_n$.

$\dashv$

3.7 Sigma completeness, put ind hvor dette passer i overstående

We can make a generalization of $D3$ by using [Lemma fra fagprojekt]. We use this generalization in some of our proofs later on. We will first need to prove the following lemma:

Lemma 3.3 Let $\tau v_0 \ldots v_{n-1}$ be a Σ_1. Then there is a recursively enumerable formula such that

$$\mathbf{PRA} \vdash \tau v_0 \ldots v_{-n1} \leftrightarrow \exists v (f v v_0 \ldots v_{n-1} = \overline{0})$$

Proof. $\dashv$

{thm:DemoSiga}

Theorem 3.9 Let $f v_0 \ldots v_{n-1}$ be a Σ_1 formula with free variables. Then:

$$\mathbf{PRA} \vdash f v_0 \ldots v_{n-1} \to \mathrm{Pr}(\ulcorner f v_0 \ldots v_{n-1} \urcorner)$$

Proof. By [ja, fra hvad?] we have that there is a Σ_1 formula $\exists v (g v v_0 \ldots v_{n-1} = \overline{0})$ such that we have:

$$\mathbf{PRA} \vdash f v_0 \ldots v_{n-1} \leftrightarrow \exists v (g v v_0 \ldots v_{n-1} = \overline{0}) \tag{3.4}$$

{eq:Com1}

and by $D1$ we have:

$$\mathbf{PRA} \vdash \mathrm{Pr}(\ulcorner f v_0 \ldots v_{n-1} \leftrightarrow \exists v (g v v_0 \ldots v_{n-1} = \overline{0}) \urcorner) \tag{3.5}$$

{eq:Com2}

We can now make the following deductions:

$$
\begin{aligned}
\mathbf{PRA} \vdash f v_0 \ldots v_{n-1} &\to \exists v (g v v_0 \ldots v_{n-1} = \overline{0}) && \text{By 3.4} \\
&\to \exists v \mathrm{Pr}(\ulcorner h v v_0 \ldots v_{n-1} = \overline{0} \urcorner) && \text{2.2} \\
&\to \mathrm{Pr}(\ulcorner \exists v (h v v_0 \ldots v_{n-1} = \overline{0}) \urcorner) && \text{By D1 and D2} \\
&\to \mathrm{Pr}(\ulcorner f v_0 \ldots v_{n-1} \urcorner) && \text{By 3.5}
\end{aligned}
$$

$\dashv$

4 Fragments of Arithmetics

In this section it will be shown how much induction there is in **PRA** and other arithmetical theories. We will look at different axioatizable subtheories of first order arithmetic called fragments. These fragments can be categories in the following three categories:

This section should be seen as overview of the subject

Strong fragments: The fragments that can prove the arithmetized cut elimination theorem.

Weak fragments: Those fragments that can not prove the arithmetized cut-elimination theorem.

Very weak fragments: The fragments which do not contain any induction axioms

We will start of by defining a very weak fragment called Robinson's theory. This fragments was first considered in [Ref]. We will denote this theory with EA for elementary aritmetics. This theory have the following axioms:

$$\forall x(\neg Sx \neq 0)$$
$$\forall x \forall y(Sx = Sy \to x = y)$$
$$\forall x(x \neq 0 \to \exists y(Sy = x)$$
$$\forall x(x + 0 = x)$$
$$\forall x \forall y(x + Sy = S(x + y))$$
$$\forall x(x \cdot 0 = 0)$$
$$\forall(x \cdot Sy = x \cdot y + x)$$

This theory dose not have the inequality symbol. We will extend Q with the following axiom:

$$x \leq y \leftrightarrow \exists z(x + z = y)$$

This extension of Q is denoted by $Q_{\leq}$

Definition 4.1 Giving a class Γ of either Σ_n or Π_n formulas we define Γ-*induction* (Γ-*ind*) to be the following schema:

$$\varphi(0) \wedge \forall v(\varphi(x) \to \varphi(Sx)) \to \forall v \varphi(v)$$

for $\varphi \in \Gamma$. Further we define Γ-*Least Number Principle* (Γ-*MIN*) to be the following schema:

$$\exists x \varphi(x) \to \exists(\varphi(x) \wedge \neg \exists y(y < x \wedge \varphi(y)))$$

For $\varphi \in \Gamma$. Lastly we will define the replacement axioms for Γ, (Γ-REPL) as the following formulas:

$$(\forall x \leq t) \exists y \varphi(x, y) \to \exists z (\forall x \leq t)(\exists y \leq z) \varphi(x, y)$$

?   ⊣

From the above axioms we can create a hierarchy of different strong fragments of arithmetics. We will define the following theories:

Definition 4.2 We define the following fragments:

1. The theory $I\Sigma_n$ is the theory that is axiomatized by the axioms of $Q_\leq$ and the Σ_n-IND axioms.

2. The theory $I\Delta_0$ is $Q_\leq$ plus the Δ_0-IND axioms.

3. The theory $L\Sigma_n$ is defined by the theory $I\Delta_0$ plus the Σ_n-MIN axioms

4. The theory $B\Sigma_n$ is defined by the theory $I\Delta_0$ plus the Σ_n-REPL axioms. The theory $I\Sigma_n^R$ is defined as the closure of $Q_\leq$ under the Σ_n induction rule:

$$\frac{F(0), \ \forall x(F(x) \to \varphi(x+1))}{\forall x F(x)}$$

5. Lastly the theory Peano arithmetics is defined as the theory Q plus induction for all first order formulas.

        ⊣

From the definition it is clear that the theory $I\Delta_0$ plays a crucial role. It can be shown that in Q a lot of the basic facts about arithmetic can be shown. These facts will not be shown here, but a list of them can be found in [Buss].

Definition 4.4 A function symbol.   ⊣

4.1 PRA

A interesting result about **PRA** is the following:

Proposition 4.1 **PRA** is the equivalent to the theory $I\Sigma_1^R$?

The proof of this is non-trivial and will go way beyond the scope of this project. The statement will not be used going forward, and its just included to give some intuition about the placement of **PRA** in the arithmetical hierarchy. The proof can be found in Artev & Bekle. This makes it possible to place **PRA** in the arithmetical hierarchy:
Figure 4.1: How the fragments relate to each other.

We will now turn to another version of the Selection Theorem.

{thm:sel}

Theorem 4.1 Let $\tau v_0 \ldots v_{n-1} v_n$ be Σ_1. There is then a Σ_1-formula $\mathrm{Sel}(\tau)$ with exactly the same free variables such that:

1. $\mathrm{Sel}(\tau) v_0 \ldots v_n \to \tau v_0 \ldots v_n$

2. $\mathrm{Sel}(\tau) v_0 \ldots v_{n-1} v_n \wedge \mathrm{Sel}(\tau) v_0 \ldots v_{n-1} v^* \to v_n = v^*$

3. $\exists v_n \tau v_0 \ldots v_{n-1} v_n \to \exists v_n \mathrm{Sel}(\tau v_0 \ldots v_{n-1} v_n$

Further this can be proven in **PRA**.

Proof. Since τ is Σ_1 it is recursively enumerable. So we have that:

$$\tau v_0 \dots v_n : \ \exists v(fvv_0 \dots v_n = \overline{0})$$

$\dashv$

4.1.1 Induction In PRA

We will further define $\mathbf{PRA}^-$ as being the sub-theory of $\mathbf{PRA}$ where we restrict us self to only having induction for p.r formulae and not Σ_1 formulae. Then we get the following result:

Proposition 4.2 Over $\mathbf{PRA}^-$ the following schemata are equivalent:

1. Σ_n-*Ind*

2. Π_n-*Ind*

3. Σ_n-*LNP*

4. Π_n-*LNP*

It shall be noted that we will only use the case of $n = 1$ going forward.

Proof. The implications $(1) \Rightarrow (4)$ and $(2) \Rightarrow (3)$ was proven in proof of theorem 4.1. The converse of these are done in the same way.

We will now show that $(1) \Rightarrow (2)$. The $(2) \Rightarrow (1)$ is similar. We will prove the case where $n = 1$, and the cases where $n > 1$ is identical, *modulo* the closure of Σ_n under bounded quantification.

So assume Σ_1-IND and suppose for $Fv \in \Sigma_1$ that the following instance of Π_1-IND fails:

$$(\neg F(\overline{0}) \wedge \forall v(\neg F(v) \to \neg F(Sv))) \to \forall v \neg F(v)$$

This means that we have $\neg F(\overline{0})$, $\forall v(\neg F(v) \to \neg F(Sv)$ and $\exists v F(v)$. We chose v_0 such that $F(v_0)$. We will use Σ_1 induction on the variable v in $F(v_0 \dot{-} v)$ to prove that $F(\overline{0})$ and get a contradiction.

Base step: It is clear that $F(v_0 \dot{-} \overline{0})$, since this is just $F(v_0)$.

Induction step: Assume that $F(v_0 \dot{-} v)$ is true. We have that $S(v_0 \dot{-} S(v)) = v_0 \dot{-} v$ unless we already have that $v = v_0$, in which case we have that $v_0 \dot{-} S(v) = v_0 - v$. So we can conclude that $\forall v F(v_0 \dot{-} v)$ and thus we have $F(\overline{0})$ and get our contradiction.

The converse of i,e $(2) \Rightarrow (1)$ is done in a similar way. $\dashv$

This means that **PRA** can do induction on Π_1 formulas, since it has induction for Σ_1 induction. It also tells us that **PRA** has the least number principle for Σ_1 and Π_1 formulas. For **PRA** the following theorem can be proven, but the proof will not be given here. But we will use theorem.

Theorem 4.2 PRA $\vdash \text{Bool}(\Sigma_1) - Ind$ where $\text{Bool}(\Sigma_1)$ is the class of combinations of Σ_1 formulae.

$$I\Pi_3^- \quad I\Sigma_2 + I\Pi_3^- \quad I\Sigma_3^-$$

$$I\Pi_2^- \quad I\Sigma_1 + I\Pi_2^- \quad I\Sigma_2^-$$

$$I\Sigma_2 \qquad I\Sigma_3^R$$

$$I\Pi_1^- \quad I\Sigma_1^-$$

$$I\Sigma_1 \qquad I\Sigma_2^R$$

$$\mathbf{Q} \qquad I\Sigma_1^R = \mathbf{PRA}$$

Figure 4.2: How the fragments relate to each other.

4.2 Expotential

If we have that $I\Gamma$ is a fragment of Peano Arithmetics, then we can look at the fragment $I\Gamma + \mathrm{EXP}$ which proves induction over Γ-formulas and proves that for all x the its power 2^x exists. We can also look at $I\Gamma + \Omega_1$ which is a weaker theory than $I\Gamma + \mathrm{EXP}$. Here Ω_1 is a axiom that asserts that for all x its power $x^{\log(x)}$ exists. It is also clear that since $\mathbf{PRA} = I\Sigma_1^R$ that these two fragments are weaker than $\mathbf{PRA}$. We will return to these two fragments later on in chapter 7.

It should here be stated that if look at theories T such that $Q_\leq \subseteq T$, then it will be possible to encode the syntax of that theory in a similar way to what we have done with $\mathbf{PRA}$; i.e in a way such that the proof predicate of that theory $\mathrm{PR}_T(x)$ is a Σ_1 formula. We will call such a theory for a *RE*-theory. We can then derive all the incompleteness result that we have obtained for $\mathbf{PRA}$ in that theory. Sometimes a little *tweaking* of the encode should be made, but we can get the following result that will not be proven here:

Theorem 4.3 Let T be a *RE*-theory such that $Q_\leq \subseteq T$. Then the following holds:

1. For any sentences F and G we get Löbs derivability conditions:

5 General Results on GL

In this section we will prove some different properties about the modal logic **GL**, that was introduced in chapter 2. These properties will be used in the following chapters. Some of these properties might hold in other modal logics, but we will look at **GL** as our base logic, instead of a more common modal logic like **K**. Further in the end we will introduce the system **GLS**.

This section will follow Smorynski 1985. But there will be a some small differences. Smorynski calls the logic **GL** for **PRL** which stands for *Pr*ovability *L*ogic, and he denotes the logic we have called **GLS** by **PRL**$^\omega$.[1]

This section (and the next one) dose not use the preceding sections about recursive functions. We will only focus on modal logic or anything about Gödel's Incompleteness Theorems. In chapter 7 we will combine all three parts; the recursion theory, the arithmetics and the modal logic.

Finiteness of W in such a model?

5.1 Tress and GL

It is known that **GL** is weakly complete with resect to conversely well-founded transitive frames. There is another result that is in the same vein; **GL** is complete with respect to finite tress. The goal of this section is to prove this result. We will first start of by defining the notion of a tree and a few results about these.

5.1.1 Trees

In this subsection the notion of a special type of graphs called tress will be introduce. The goal of this section is to prove Könings lemma about trees. We will start of by defining the notion of a tree.

Definition 5.1 A *tree* is a tuple $\mathcal{T} = \langle W, R, w_0 \rangle$ where (W, R) where:

1. $<$ is transitive and asymmetric.

2. w_0 is the minimal element of $<$. I.e $w_0 < w$ for all $w \in W$.

---

[1]He also have a slightly different definition of a Kripke model.

3. The set of predecessors of any element is finite and linearly ordered by $<$.

A tree is *infinite* if the set W is infinite. ⊣

We will state some immediate definitions, that should be known from the course *Diskret matematik*:

Definition 5.2 The *nodes* of a tree $\mathcal{T} = \langle W, R, w_0 \rangle$ are the elements of the set W.
If $w, v \in W$ are nodes and wRv then we say that they are joined by an *edge*.
A *walk* is an altering series of vertices and edges in which for each v we have that wRv for the w immediate before it . We call a walk for a *trail*, if all the edges in the walk are distinct. A *path* is trail in which all the nodes are different. ⊣

It is know from the course *Diskret matematik* that between any two vertices there are exactly one path in a tree. As the concept of a tree is assumed know, we will not look at any concrete examples, We will need some further definitions to state and prove Könings lemma:

Definition 5.3 Let $w \in W$. The *degree* of of w in $\mathcal{T}$ is the number of edges incident to it. ⊣

Definition 5.4 Let w be a node of a tree $\mathcal{T}$, we then define the map $\pi : \mathcal{T} \backslash \{w_0\} \to \mathcal{T}$ in the following way:

$$\pi(w) = \text{The node adjacent to } w \text{ on the path to } w_0$$

We call $\pi(w)$ the *parent node* of w.
The *child nodes* of w are the elements of the set $\{v\mathcal{T} : \pi(v) = w\}$, i.e the child nodes of w are all the nodes of $\mathcal{T}$ to which w is the parent. If w has no child nodes it is called a *leaf node*. ⊣

It is clear that if w is a leaf node, then degree of w is 1.

Definition 5.5 A subset Γ of a tree $\mathcal{T}$ is called a *branch* if and only if all the following conditions holds:

1. $w_0 \in \Gamma$

2. The parent node of each $w \in \Gamma \setminus \{w_0\}$ is in Γ

3. Each node in Γ is either a leaf node in $\mathcal{T}$ or has exactly one child node in Γ.

A branch Γ is called *infinite* if and only if it has no leaf node at the end. ⊣

Definition 5.6 A *fork* of a $\mathcal{T}$ is a node of $\mathcal{T}$ which is the end point of two or more branches. ⊣

Definition 5.7 A tree $\mathcal{T}$ is called a *finitely branching tree* if every node of $\mathcal{T}$ has finitely many child nodes. ⊣

The proof of Könings lemma will depend on the following axiom:

Axiom 5.1 (Axiom of Dependent Choice) Let R be an relation on a set W and suppose that:
$$\forall w \in W \exists v \in W : wRv$$

Then there exists a sequence $(w_n)_{n \in \omega} \in W$ such that

$$\forall n \in \omega : w_n R w_{n+1}$$

This axiom is a weak form of the axiom of choice, so some of the consequnces of the axiom of choice also follows from this axiom. **Er dette overhovedt vigtigt at kommentere på?**

In the proof of Köning's lemma we will look at the subset of all nodes with infinitely many descendants and the relation R where we have that for nodes $w, v \in W$: wRv if and only if v is a child of w. This relation and set fulfills the conditions of the axiom and we can thus create the sequence $(w_n)_{n \in \omega}$.

We can now state Köning's lemma:

Lemma 5.1 Köning's lemma Let $\mathcal{T}$ be a finitely branching tree. Then it is infinite if and only if has an infinite path.

`{lem:kong}`

Proof. If $\mathcal{T}$ has an infinite path, then it is trivial true that $\mathcal{T}$ is infinite.

For the other way, assume that $\mathcal{T}$ is infinite. To show that $\mathcal{T}$ has an infinite path is the same as showing that it has an infinite branch. We will show that there is a sequence of nodes $w = (w_0, w_1, w_2, \ldots)$ in $\mathcal{T}$ such that the following holds:

1. w_0 is the root node

2. w_{n+1} is a child node of t_n

3. each w_n has infinitely many descendants (definer dette, selvom det giver god mening).

Then w is a branch of infinite length, and thus $\mathcal{T}$ has an infinite path.

We start with the root node w_0. It has a finite number of child nodes. Suppose for contradiction that each of these child nodes had a finite number of descendants, but thus would mean that w_0 would have a finite number of descendants and thus that $\mathcal{T}$ would be finite. Therefore w_0 has a child node with infinitely many descendants; let w_1 be one of those.

Now suppose that node w_k has infinitely many descendants. By the same argument as before we get that w_k has at least one child node with finitely many

descendants. Let w_{k+1} be one of these. We have thus shown how the sequence w can be constructed, and the lemma follows by the axiom of dependent choice ⊣

It is clear that finite trees are conversely well-founded frames. This fact is crucial in the proof of theorem in the next subsection, that can be seen as strengthening of the weak completeness theorem of chapter 2:

5.1.2 The Finite Tree Theorem

The following theorem is a strengthening of the weak completeness theorem for **GL**, since trees are a subset of the transitive conversely well-founded models and we by this theorem get that we can with out loss of generality assume that our model is finite. This last feature will be crucial in the proof of main theorems of the next chapter.

Theorem 5.2 (The Finite Tree Theorem) Let α be a modal formula. Then the following are equivalent:

1. $\vdash_{\mathbf{GL}} \alpha$

2. α is true in all models on finite trees

3. α is valid in all models on finite trees

With this theorem it is possible to only consider finite frames. This will make the proof of our main theorem of chapter 7 possible.

Proof. The implications $(1) \Rightarrow (2)$ and $(1) \Rightarrow (3)$ follows by the completeness theorem. We also have that $(2) \Leftrightarrow (3)$ is true [Kom med et kort argument]. Thus we will just have to show $(2) \Rightarrow (1)$

We will show this by contraposition, i.e $\neg(1) \Rightarrow \neg(2)$. Assume that $\nvdash_{\mathbf{GL}} \alpha$ and let $\mathcal{K}$ be the following model $\mathcal{K} = \langle W, R, w_0, \phi \rangle$ be a counter model i.e $\nvDash_{w_0}^{K'} \alpha$. Let S be the set of subformulas of α The goal is now to define a finite tree model: $\mathcal{K}_T = \langle W_T, <_T, \phi_T \rangle$. We will do this be letting W_T consists of finite R-increasing sequences form K.

Stage 0: Let the sequence w_0 be a part of K_T.

Stage $n+1$: For each sequence $(w_0, \ldots w_n) \in W_T$ we will look at $\Gamma = \{\Box\beta \in S(\alpha) : w_n \in \phi(\Box\beta)\}$. If $\Gamma = \emptyset$ then we do not extend the sequence $(w_0, \ldots w_n)$. Otherwise we will for each $\Box\beta \in \Gamma$ choose a node $v \in W$ such that $w_0 R v$ and such that we have:

$$v \in \phi(\Box\beta), \ v \notin \phi(\beta)$$

We can do this because of axiom 3. We will then add the sequence $(w_0, \ldots w_n, v)$ to the set W_T

The model $\mathcal{K}_T$ then further consists of $<_T$ is the strict ordering by extension of finite sequences. ϕ_T is the defined in the following way:

$$(w_0, \ldots, w_n) \in \phi_T(p) \Leftrightarrow w_n \in \phi(p)$$

This leads way to the following notation that we will use in the rest of the proof:

$$\vDash^{\mathcal{K}_T}_{(w_0, \ldots, w_n)} p \Leftrightarrow \vDash^{\mathcal{K}}_{w_n} p$$

We will now prove two claims, by which the theorem will follow

Claim 1: $\mathcal{T} = (W_T, <_T, w_0)$ is a finite tree with origin (w_0). Finiteness follows from lemma 5.1, since the $\mathcal{T}$ is finitely branching since the branches correlated with the elements of S. Further there is no infinite paths in $\mathcal{T}$, since when we go from $(w_0, \ldots w_n)$ to $(w_0, \ldots, w_n, w_{n+1})$ we one sentence from $\Box\beta \in S$ gets forced by w_{n+1} and since these are finite, the process will stop at some point, and thus the path will be finite.

Claim 2: For all $\beta \in S(\alpha)$ and for all $(w_0, \ldots w_n) \in W_T$ we have:

$$\vDash^{\mathcal{K}_T}_{(w_0, \ldots, w_n)} \beta \Leftrightarrow \vDash^{\mathcal{K}}_{w_n} \beta$$

This proof is done by induction on the complexity of β. We will only look at the case $\beta = \Box\gamma$. So we have by the induction hypothesis:

$$\begin{aligned}
\vDash_{w_0} \Box\gamma &\Rightarrow \forall v(w_0 R v \Rightarrow \vDash_v \gamma) \\
&\Rightarrow \forall v((w_0, \ldots w_n, v) \in W_T \Rightarrow \vDash_v \gamma) \\
&\Rightarrow \forall v((w_0, \ldots w_n, v) \in W_T \Rightarrow \vDash^{\mathcal{K}_T}_{(w_0, \ldots w_n, v)} \gamma)
\end{aligned}$$

And the last line is the same as $\vDash_{(w_0, \ldots, w_n)} \Box\gamma$ For the other way, we will use contraposition:

$$\begin{aligned}
\nvDash_{w_0} \Box\gamma &\Rightarrow \exists v(w_0 R v \And \nvDash_v \gamma) \\
&\Rightarrow \exists v((w_0, \ldots w_n, v) \in W_T \And \nvDash_v \gamma) \\
&\Rightarrow \exists v((w_0, \ldots w_n, v) \in W_T \And \nvDash^{\mathcal{K}_T}_{(w_0, \ldots, w_n, v)} \gamma)
\end{aligned}$$

And the last line is the same as $\nvDash_{(w_0, \ldots, w_n)} \Box\gamma$.

The theorem now follows since we have:

$$\nvDash_{w_0} \alpha \Rightarrow \nvDash^{\mathcal{K}_T}_{[w_0)} \alpha$$

$\dashv$

From this theorem there follows a number of interisting corrolaies:

47

Corollary 5.1 GL is decidable.**Definer lige hvad dette betyder**

{cor:Nec}

Corollary 5.2 For all formulas α we have:

$$\vdash_{\mathbf{GL}} \alpha \Leftrightarrow \vdash_{\mathbf{GL}} \Box\alpha$$

From this theorem, we can also find the minimum element of a Kripke model of **GL**. This leads to the following definition:

Definition 5.8 Let $\mathcal{K} = \langle W, R, \phi \rangle$ be a Kripke model. A *pointed Kripke model* is a pair $\langle \mathcal{K}, w_0 \rangle$ where w_0 is a node of W. In the rest of this project we will have that w_0 is the minimum node of the tree of **GL**. We will often just define a pointed Kripke as $\mathcal{K} = \langle W, R, \phi, w_0 \rangle$. ⊣

5.2 The Continuity Theorem

In this section the continuity theorem and a corollary of it will be stated and proven. This section applies to all Kripke model, and thus is not only about **GL**.
    We will first need to definitions:

Definition 5.9 We define $d(\alpha)$ in the following way: $d(p) = d(\bot) = 0$, $d(\alpha \to \beta) = \max(d(\alpha), d(\beta))$ and $d(\Box(\alpha) = d(\alpha) + 1$. So $d(\alpha)$ is the maximal number of nested occurences of $\Box$ in α. We call $d(\alpha)$ the modal degree of α. ⊣

Definition 5.10 Let R be a relation on a set W. For each $i \in \omega$ define R^i as follows: R^0 is the identity relation on W. $R^{i+1} = \{\langle w, v \rangle : \exists v'(wR^i v' \land v'Rv\}$. This $R^1 = R$ and $wR^n v$ if and only if $\exists v_0, \ldots v_n(w = v_0 R \ldots R v_n = v)$. ⊣

{thm:conti}

Theorem 5.3 (The Continuity Theorem) Let $\mathcal{K} = \langle W, R, \phi \rangle$ and $\mathcal{K}' = \langle V, S, \phi' \rangle$ be models and let $w \in W$. Let $P \subseteq \Phi$ be a set of proportional letters. Suppose that $d(\alpha) = n$, that all proportional letters that occur in α are in P, $\{v : \exists i \le n \ wR^i v\}$, $S = \{\langle v, v' \rangle : x, y \in V \land vRv'\}$, and $p \in \phi'(v)$ if and only if $p \in \phi(v)$ for all $v \in V$ and all proportional letters in P. Then $\vDash_w^{\mathcal{K}} \alpha$ if and only if $\vDash_w^{\mathcal{K}'} \alpha$.

Proof. We will show that for all subformulas β of α, if we for some i have that $wR^i v$ and $d(\beta) + i \le n$ such that $i \le n$ and $v \in V$, then $\vDash_v^{\mathcal{K}} \beta$ if and only if $\vDash_v^{\mathcal{K}'} \beta$. Since $wR^0 w$ and $d(\alpha) = 0$ the theorem will follow.
    The proof will be induction on the complexity if β. The cases where β is $\bot$ or a $p \in P$ is trivial. If β is $\gamma \to \sigma$ then $d(\gamma), d(\sigma) \le d(\beta)$ and the result follows the induction hypothesis. If β is , $WR^i v$ and $d(\beta) + i \le n$. Then $v \in V$ and $d(\beta) = d(\gamma) + 1$. If vRv' then $wR^{i+1} v'$, $d(\gamma) + i + 1 \le n$, $v' \in V$ and therefore vSv' and by the induction hypothesis we get $\vDash_{v'}^{\mathcal{K}} \Gamma$ if and only if $\vDash_{v'}^{\mathcal{K}'} \gamma$, since we have that $S \subseteq R$, vRv' if vSv'. But this means that $\vDash_v^{\mathcal{K}} \beta$ if and only if for all v' such

that vRv' we have that $\vDash_{v'}^{\mathcal{K}'} \gamma$; if and only if for all v' such that vSv': $\vDash_{v'}^{\mathcal{K}} \gamma$ if and only if by the induction hypothesis for all v' such that vSv'; $\vDash_{v'}^{\mathcal{K}'} \gamma$ if and only if $\vDash_{v}^{\mathcal{K}'} \beta$. ⊣

From this theorem the following corollary is a immediate consequence and we will use it to prove parts of the main theorem of the next chapter:

{cor:conti}

Corollary 5.3 Let α be a formula. Let $\mathcal{K} = \langle W, R, \phi \rangle$ and $\mathcal{K}' = \langle V, R, \phi' \rangle$ be models, and $p \in \phi(w)$ if and only if $p \in \phi'(w)$ for all $w \in W$ and all p contained in α. Then $\vDash_{w}^{\mathcal{K}} \alpha$ if and only if $\vDash_{w}^{\mathcal{K}'} \alpha$.

5.3 The system GLS

In this section we will define the modal logic **GLS** (The "S" is for Solovay). Before we can do this in a smart way, we will define the notion of a Nec free axiomation; i.e a system that is not closed under the rule Nec. We have to do this, since the system **GLS** will extend **GL** but is not closed under the rule nec.

5.3.1 Avoiding Nec

In this section we will take **K4** as our base logic and see **GL** as an extension of this. We will need the following notation to define this. Given a set Γ:

1. $\Gamma \vdash_{\mathbf{MP}} \alpha$ if α is derivable form Γ by only using $R1$

2. $\Gamma \vdash_{\mathbf{Nec}} \alpha$ if α is derivable form Γ by using $R1$ and $R2$.

We will further define the following set for any set Γ:

$$\Gamma^{\mathbf{Nec}} = \Gamma \cup \{\Box\beta : \beta \in \Gamma\}$$

This set allows us to avoid Nec by the axioms of **K4**, which the following lemma shows:

Lemma 5.1 Let Γ include all the instances of axioms of **K4**. Then:

$$\Gamma \vdash_{\mathbf{Nec}} \alpha \Leftrightarrow \Gamma^{\mathbf{Nec}} \vdash_{\mathbf{MP}} \alpha$$

Proof. The way $\Leftarrow$ is trivial. So we will only show $\Rightarrow$. To prove this, it is enough to show that the set of theorems of $\Gamma^{\mathbf{Nec}}$ is closed under $R2$; i.e to show that:

$$\Gamma^{\mathbf{Nec}} \vdash \alpha \Rightarrow \Gamma^{\mathbf{Nec}} \vdash_{\mathbf{MP}} \Box\alpha$$

Let $\Gamma^{\mathbf{Nec}} \vdash_{\mathbf{MP}} \alpha$. Then we have a sequence $\alpha_1, \ldots, \alpha_n = \alpha$, where for each $1 \leq i \leq n$ we have that α_i is one of the following three:

1. We have that it is an axiom $\alpha_i \in \Gamma$

2. It is the necessitation $\square\beta_1$ of an axiom $\beta_1 \in \Gamma$

3. It is a consequence of **MP** of $\alpha_j, \alpha_k = \alpha_j \to \alpha_i$ where $j, k < i$.

We will show by induction on the length i of a 'initial' segment $\alpha_1, \ldots, \alpha_i$ that $\Gamma^{\mathbf{Nec}} \vdash_{\mathbf{MP}} \square\alpha_i$.

1. If we have that $\alpha_i \in \Gamma$. Then by definition we have that $\square\alpha_i \in \Gamma^{\mathbf{Nec}}$ and thus $\Gamma^{\mathbf{Nec}} \vdash_{\mathbf{MP}} \square\alpha_i$.

2. If $\alpha_i = \square\beta_i$ for some $\beta_i \in \Gamma$, then we can make the following deduction:

$$
\begin{aligned}
\Gamma^{\mathbf{Nec}} &\vdash_{\mathbf{MP}} \square\beta_i & &\text{Since } \square\beta_i \in \Gamma^{\mathbf{Nec}} \\
&\vdash_{\mathbf{NP}} \square\beta_i \to \square\square\beta_i & &\text{By } \mathbf{4} \\
&\vdash_{\mathbf{MP}} \square\square\beta_i \ (= \square\alpha_i) & &\text{By } \mathbf{MP}
\end{aligned}
$$

Which shows the result.

3. If α_i follows form $\alpha_j, \alpha_k = \alpha_j \to \alpha_i$ by **MP** we have by the induction hypothesis that $\Gamma^{\mathbf{Nec}} \vdash_{\mathbf{MP}} \square\alpha_j$ and $\Gamma^{\mathbf{Nec}} \vdash_{\mathbf{MP}} \square(\alpha_j \to \alpha_i)$. By **K** we also have that $\Gamma^2 \vdash_{\mathbf{MP}} \square\alpha_j \wedge \square(\alpha_j \to \alpha_i) \to \square\alpha_i$ and by propositional logic we get that: $\Gamma^2 \vdash_{\mathbf{MP}} \square\alpha_i$.

This ends the induction and the lemma will follow. $\dashv$

By this lemma we can get a **Nec**-free definition of **K4** and **GL** that we will call $\mathbf{K4}^{\mathbf{Nec}}$ and $\mathbf{GL}^{\mathbf{Nec}}$. We can further by the deduction theorem from propositional logic get the following:

Lemma 5.2 $\Gamma \vdash \alpha$ iff there is a finite set $\{\gamma_0, \ldots, \gamma_{n-1}\} \subseteq \Gamma$ such that: $K \vdash \wedge \gamma_i \to \alpha$

5.3.2 Definition of GLS

Definition 5.11 The system of modal logic **GLS** is defined as the system of propositional modal logic that have all the theorems of $\mathbf{GL}^{\mathbf{Nec}}$ and addition of the axiom of Reflexion:

Refl: $\square\alpha \to \alpha$

and which sole rule of inference is *modus ponens*. $\dashv$

It should be noted that this modal logic is not a *normal* one. The main theorem about this modal logic is the following, which gives a sort of model theory for **GLS**.

{hm:MainGLS}

Theorem 5.4 Let α be a modal formulas. Define the following set: $S_\square(\alpha) = \{\square\beta : \square\beta$ is a subformula of $\alpha\}$ the set of subformulas of α that is boxed. Then the following to statements are equivalent:

1. $\vdash_{\mathbf{GLS}} \alpha$

2. $\vdash_{\mathbf{GL}} \bigwedge_{\square\beta\in S_\square(\alpha)}(\square\beta \to \beta) \to \alpha$

This theorem reduces the decidability of **GLS** to the decidability of **GL** and describes a model theory for **GLS**.

Definition 5.12 A model $\mathcal{K} = \langle W, R, \phi \rangle$ with start node w_0 is α-sound if for every $\square\beta \in S_\square(\alpha)$ we have: $\vDash_{w_0} \square\beta \to \beta$ $\dashv$

We can reduce theorem 5.4 to the following:

{thm:lll}

Theorem 5.5 Let α be a modal formulas. Then:

1. $\vdash_{\mathbf{GLS}} \alpha$ iff α is true in all α-sound models of **GL**

2. $\vdash_{\mathbf{GL}} \alpha$ iff α is valid in all α-sound models of **GL**

Proof that 5.5 $\Rightarrow$ 5.4: Assume 5.5.1. We hen have that $\vdash_{\mathbf{GLS}} \alpha$ iff α is true in all α-sound models of **GL**; which is the same all models of $\mathbf{GL} + \bigwedge_{\square\beta\in S_\square(\alpha)}(\square\beta \to \beta) = \mathbf{GL}^s$ and hence:

$$\vdash_{\mathbf{GLS}} \alpha \Leftrightarrow \vdash_{\mathbf{GL}^s} \alpha$$

$\dashv$

From theorem 5.5 we get the following corollary:

Corollary 5.4 Let α be a modal formula. Then:

$$\vdash_{\mathbf{GL}} \alpha \Leftrightarrow \vdash_{\mathbf{GLS}} \square\alpha$$

Proof. ""$\Rightarrow$": We have that

$$\vdash_{\mathbf{GL}} \alpha \Rightarrow \vdash_{\mathbf{GL}} \square\alpha, \text{ By closure under nec}$$
$$\Rightarrow \vdash_{\mathbf{GLS}} \square\alpha$$

51

"”$\Leftarrow$”: We see that we have

$$\vdash_{\textbf{GLS}} \Box\alpha \;\Rightarrow\; \Box\alpha \text{ is true in all } \Box\alpha\text{-sound model of } \textbf{GL}$$
$$\Rightarrow \vdash_{\textbf{GL}} \Box\alpha$$
$$\Rightarrow \vdash_{\textbf{GL}} \alpha$$

Where the last deduction follows form corollary 5.2. $\qquad\dashv$

For the proof of 5.5 we will make use of the following usefull construction:

Definition 5.13 Let $\mathcal{K} = \langle W, R, \phi \rangle$ be a Kripke Model. The derived model $\mathcal{K}'$ is defined as follows: $W' = W \cup \{w'\}$, where $w' \notin W$. We further have that R' is defined as $wR'v$ iff WRv for $w, v \in W$; w' is the new minimum element. Lastly we have that $w \in \phi'(p)$ iff $w \in \phi(p)$ for $w \in K$, where p is any atomic formula. Further we have that $w' \in \phi'(p)$ iff $w_0 \in \phi(p)$. $\qquad\dashv$

We can further define the notion of a sequences of successive derived models: $\mathcal{K}^{(1)}, \mathcal{K}^{(2)}, \ldots$ that have $w_1, w_2, \ldots$ as their minima. We define $\mathcal{K}^{(1)} = \mathcal{K}$ and $\mathcal{K}^{(n+1)} = (\mathcal{K}^{(n)})'$ and let w_n denote the minimum of $\mathcal{K}^{(n)}$. This can graphically been seen by adding a tail of n nodes below w_0, as seen in the following graphs:

Figure 5.1: The visualization of the models $\mathcal{K}$ (left) and $\mathcal{K}^{(n)}$ (right)

It should be noted that for $w \in \mathcal{K}$ and for any formula γ that we have:

$$\vDash_w \gamma \text{ in } \mathcal{K} \Leftrightarrow \vDash_w^{(n)} \gamma \text{ in } \mathcal{K}^{(n)}$$

For the rest of this project we will omit the annoying superscripts.

The following lemma will explain a bit deeper how these derived models works:

Lemma 5.3 Let $\mathcal{K}$ be a α-sound model, $S(\alpha)$ the set of subformulas of α and $\mathcal{K}^{(n)}$ be the n-derived model. Then for all $\beta \in S(\alpha)$ we have:

$$\vDash_{w_0} \beta \Leftrightarrow \vDash_{w_n} \beta$$

Proof. We will prove this by induction on n. The lemma will follow from the case $n = 1$ [Why?], and this will be proven by induction om complexity of β. The only non trivial case is the case where $\beta = \Box\gamma$, so this is the only case that will be shown:

Let $\beta = \Box\gamma \in S(\alpha)$.

($\Rightarrow$) The following is clear for $\Box\gamma \in S(\alpha)$:

$$\vDash_{w_0} \Box\gamma \Rightarrow \vDash_{w_0} \gamma$$

This follows since our model is α-sound. Therefore we have: $\forall v > w_1(\vDash_{w_1} \gamma)$ and thus $\vDash_{w_1} \Box\gamma$

($\Leftarrow$) Here we can make the following deduction:

$$\begin{aligned}
\vDash_{w_1} \Box\gamma &\Rightarrow \forall v > w_1(\vDash_v \gamma) \\
&\Rightarrow \forall v > w_0(\vDash_v \gamma) \\
&\Rightarrow \vDash_{w_0} \Box\gamma
\end{aligned}$$

$$\dashv$$

We can now return to our proof of the main theorem of this section by proving 5.5

Proof of 5.5. We will start of by proving (1). One way is easy:

($\Leftarrow$) If α is true in all α-sound models $\mathcal{K}$ of **GL** then:

$$\vdash_{\mathbf{GL}^s} \alpha$$

And therefore we have $\vdash_{\mathbf{GLS}} \alpha$.

($\Rightarrow$) This way takes a bit more work; it will be proven by contraposition. So suppose that α is false in α-sound model $\mathcal{K} = \langle W, R, \phi \rangle$. Then we have:

$$\vDash_w \bigwedge_{\Box\beta \in S_\Box(\alpha)} (\Box\beta \to \beta)$$

But still also have: $\nvDash_{w_0} \alpha$. We will show that $\nvdash_{\mathbf{GLS}} \alpha$ by showing that for any finite set Γ that for the system $\mathbf{GL}^\Gamma = \mathbf{GL} + \bigwedge_{\gamma \in \Gamma} (\Box\gamma \to \gamma)$ that we have:

$$\nvdash_{\mathbf{GL}^\Gamma} \alpha$$

By lemma 5.3 we have that every model in the sequence $\mathcal{K}^{(0)}, \mathcal{K}^{(1)}, \dots$ is an α-sound model, wherein α is false. We will just have to show that for any finite set Γ that is a number m such that:

$$\vDash_{w_m} \bigwedge_{\gamma \in \Gamma} (\Box\gamma \to \gamma)$$

This can be shown by showing that there is a m such that for each $n > m$ that the following holds:

$$\vDash_{w_n} \Box\gamma \to \gamma$$

But we either have that $\vDash_{w_m} \Box\gamma$ for all n, thus $\vDash_{w_n} \gamma$ for all n; or we have $\nvDash_{w_m} \Box\gamma$ for some m and thus $\nvDash_{w_n} \Box\gamma$ and $\vDash_{w_n} \Box\gamma \to \gamma$ for al $n > m$. This shows (1). We will now prove (2).

The way "$\Rightarrow$" is trivial since if $\vdash_{\mathbf{GL}} \alpha$ then α is valid in all models of $\mathbf{GL}$ and hence in all α-sound models of $\mathbf{GL}$.

For the implication $\Leftarrow$, we will assume that α is valid in all α-sound models. Again set $\mathbf{GL}^s$ to be $\mathbf{GL} + \bigwedge_{\Box\beta \in S_\Box} (\Box\beta \to \beta)$. Then we have that show that:

$$\vdash_{\mathbf{GL}^s} \alpha \Rightarrow \vdash_{\mathbf{GL}} \alpha$$

We show this by contraposition. So assume that $\vdash_{\mathbf{GL}} \neg\alpha$. We get $\mathbf{GL}^s$ be adding a finite amount of formulae to $\mathbf{GL}$ and thus we have that $\vdash_{\mathbf{GL}^s} \neg\alpha$. $\dashv$

In the chapter 7 it will be shown that $\mathbf{GL}$ axiomatise the provable schemata in $\mathbf{PRA}$ and $\mathbf{GLS}$ will axiomatise the *true* schemata of arithmetics; i.e truth in the standard model $\mathcal{N} = \langle \omega, +, \cdots \rangle$ of arithmetics.

6 Fixed Point Theorem

In this section we will prove the so called *fixed point theorem* for **GL**. This theorems says that there for some sentences of **GL** exists fixed points. There has been a lot of different ways to prove this theorem; Boolos list three different ways in his book George. S Boolos 1993 Here we will follow the proof from Reidhaar-Olson 1990.

Before stating the theorem, we will have to state the following definitions:

Definition 6.1 We abbreviate $\Box\alpha \wedge \alpha$ as $\boxdot\alpha$ for every α in our langauge. $\quad\dashv$

$\boxdot$ is called "strong box".

Remark 6.1 By our semantic of modal logic, this we have that $\vDash_w \boxdot\alpha$ is true iff $\vDash_v \alpha$ for all $v \in \{w\} \cup \mathrm{acc}(w)$, where $\mathrm{acc}(w)$ are $\mathrm{acc}(w)$ is the collection of "states" that can be "seen" from w, i.e: $\mathrm{acc} = \{v \in W : wRv\}$

Another useful definition that we can make, since we for every Kripke model $\mathcal{K} = \langle W, R, \phi \rangle$ of **GL** have that W is a finite set is the following:

Definition 6.2 Let $\mathcal{K} = \langle W, R, \phi \rangle$ be a Kripke model of **GL**. The *rank* of the notes $w \in W$ is defined in the following way: $\mathrm{rank}(w) = 0$ iff there is no world v such that wRv. Otherwise we have that $\mathrm{rank}(w) = 1 + \mathrm{maxrank}(v) : wRv\}$. $\quad\dashv$

Since W is finite and that R is irreflexive we have that the for each $w \in W$ the $\mathcal{K}$-rank of w is unique.

We will need the following three lemmas in our proof of the Fixed Point Theorem:

Lemma 6.1 Given any Kripke model $\mathcal{K}) \langle W, R, \phi \rangle$ of **GL**, $w \in W$ and sentence α, we have that if $\vDash_w \Box\alpha$ then $\vDash_v \Box\alpha$ for any $v \in \mathrm{acc}(w)$. Further we have that $\vDash_v \boxdot\alpha$ for all $x \in \mathrm{acc}(w)$.

Proof. Assume that we have $\vDash_w \Box\alpha$, w sees v and v sees v'. Since R is transitive we have that w is also connected to v' and thus we have that $\vDash_{v'} \alpha$. Since v' was chosen at random we have that $\vDash_v \Box\alpha$. We also have that $\vDash_v \alpha$ and thus we have $\vDash_v \boxdot\alpha$. $\quad\dashv$

Lemma 6.2 Given any Kripke model $\mathcal{K} = \langle W, R, \phi \rangle$, $w \in W$ and sentence α, if $\nvDash_w \Box\alpha$ then there is "notes" v connected to w such that $\vDash_v \Box\alpha$ and $\nvDash_v \alpha$.

Proof. Assume that $\nvDash_w \Box\alpha$ then there is a notes v connected to w such that $\nvDash_v \alpha$. Let v be the notes with the least rank with this property and suppose that vRv'. Since v' is of less rank than v we have that $\vDash_{v'} \alpha$. Now since v' was chosen arbitrarily we have that $\vDash_v \Box\alpha$ and the lemma is proven. $\dashv$

The next lemma will be crucial in the proof of the fixed-point theorem.

{lem:sem}

Lemma 6.3 (Semantic Substitution Lemma) For any sentences α, β and γ we have that the following formula is valid in all models of **GL**:

$$\boxdot(\beta \leftrightarrow \gamma) \to (\alpha(\beta) \leftrightarrow \alpha(\gamma))$$

The meaning of $\alpha(\beta)$ is that we replace every occurrences of p in α with β; the meaning of $\alpha(\gamma)$ is similar.

Proof. We start of by fixing β and γ. The proof will be by induction on the complexity of α. We will only proof the part where α is $\Box\sigma$.

So suppose that α is $\Box\sigma$, where $\boxdot (\beta \leftrightarrow \gamma) \to (\sigma(\beta) \leftrightarrow \sigma(\gamma))$ is valid. Let $\mathcal{K}$ be any model of **GL** and let $w \in W$. Suppose that $\vDash_w\boxdot (\beta \leftrightarrow \gamma)$. Let v be any world seen by w. Then by lemma 6.1 we have $\vDash_v\boxdot (\beta \leftrightarrow \gamma)$. Since $\boxdot (\beta \leftrightarrow \gamma) \to (\sigma(\beta) \leftrightarrow \sigma(\gamma))$ is valid we get that $\vDash_v \sigma(\beta) \leftrightarrow \sigma(\gamma)$ and since v was chosen arbitrary we get $\vDash_w \Box(\sigma(\beta) \leftrightarrow \sigma(\gamma))$. By proposition 2.2 and weak completeness we can conclude $\vDash_w \Box\sigma(\beta) \leftrightarrow \sigma(\gamma)$. $\dashv$

We are now almost ready to state state and prove the fixed-point theorem. We will just need the next to definitions:

Definition 6.3 A sentence α is called modalized in p if every occurence of p in α is under the scope of $\Box$. $\dashv$

We will also need the following definition:

Definition 6.4 A sentence α is said to be *n-decomposable* iff for some sequence $q_1, \ldots, q_n$ consisting of distinct senctence letters that do not occur in α we have some sentence $\beta(q_1, \ldots, q_n)$ that do not contain p and another sequence of distinct sentences $\gamma_1(p), \ldots, \gamma_n(p)$, which each contains p that we have

$$\alpha = \beta(\gamma_1(p), \ldots, \gamma_n(p))$$

. $\dashv$

It should be noted that if α is modalized in p that we then have that α is n-decomposable for some n.

We can now state the fixed point theorem.

Theorem 6.1 If α is modalized in p, then there exists a formula σ in which the only sentence letters that occurs are these other than p that occur in α, and such that:

$$\boxdot(p \leftrightarrow \alpha) \rightarrow (p \leftrightarrow \sigma)$$

The formula σ is called a *fixed-point* of α.

We will later on proof that $\vdash_{\mathbf{GL}} \sigma \leftrightarrow \alpha(\sigma)$ for such a σ and thus the name fixed point makes sense.

Proof. We will prove this by showing that if α is n-decomposable then it has a fixed point. We will show this by induction on n.

Base case: Suppose that α is 0-decomposable. Then we have that p dose not occur in α and it can thus itself be the sentence β.

Induction step: Assume that every sentence that is n-decomposable has a fixed point. We now have to show that every sentence that is $(n+1)$-decomposable also has a fixed point. To show this we will assume the following:

$$\alpha(P) = \beta(\Box\gamma_1(p), \ldots, \Box_{n+1}(p))$$

Further for each i let:

$$\alpha_i(p) = \beta(\Box\gamma_1(p), \ldots, \Box\gamma_{i-1}, \top, \Box\gamma_{i+1}, \ldots, \Box\gamma_{n+1}(p))$$

Thus we have that for each i that $\alpha(p)$ is n-decomposable, so it has a fixed point, that we call σ_i. Lastly we define:

$$\sigma = \beta(\Box\gamma_1(\sigma_1), \ldots, \Box\gamma_{n+1}(\sigma_{n+1}))$$

Our goal is to show that σ is a fixed point of α.

Lemma 6.4 For each i we have that:

$$\vdash_{\mathbf{GL}}\boxdot(p \leftrightarrow \alpha) \rightarrow\boxdot\Box\gamma_i(p) \leftrightarrow \gamma_i(\sigma_i))$$

Proof. Since we have that **GL** is complete, we just ave to show that for any model $\mathcal{K} = \langle W, R, \phi \rangle$ and any $w \in W$ that:

$$\mathcal{K} \vDash\boxdot(p \leftrightarrow \alpha) \rightarrow\boxdot(\Box\gamma_i(p) \leftrightarrow \Box\gamma_i(\sigma_i)) \tag{6.1}$$

So we will start of by fixing i, $\mathcal{K}$ and $w \in W$. We will show 6.1 by assuming $\vDash_w\boxdot(p \leftrightarrow \alpha)$ and then deduce: $\vDash_w\boxdot(\Box\gamma_i(p) \leftrightarrow \Box\gamma_i(\sigma_i))$; this is equivalent to $\vDash_v \Box\gamma_i(p) \leftrightarrow \Box\gamma_i(\sigma_i)$ for all $v \in \{w\} \sup \mathrm{acc}(w)$ by remark 6.1. So let $v \in \{w\}\cup\mathrm{acc}(w)$

and assume that $\vDash \Box\gamma_i(p)$, i.e $\vDash_v \Box\gamma_i(p) \leftrightarrow \top$. By lemma 6.1 we have that for any $v' \in \mathrm{acc}(v)$ that $\vDash_{v'} \Box\gamma_i(p)$ and thus $\vDash_{v'} (\Box\gamma_i(p) \leftrightarrow \top)$. This means that we have:

$$\vDash_v \boxdot(\Box\gamma_i(p) \leftrightarrow \top)$$

And thus by lemma 6.3 we get that $\vDash_v \alpha_i \leftrightarrow \alpha$ and since our v was chosen arbitrarily we have that $\vDash_w \Box(\alpha_i \leftrightarrow \alpha)$ and thus by lemma 6.1 we get that: $\vDash_v \boxdot(\alpha_i \leftrightarrow \alpha)$. Since we have assumed that $\vDash_w \boxdot(p \leftrightarrow \alpha)$ we again have by lemma 6.1 that $\vDash_v \boxdot(p \leftrightarrow \alpha)$, and hence we have $\vDash_v \boxdot(p \leftrightarrow \alpha_i)$. Since our logic is complete and we have assumed by the induction hypothesis that α_i has a fixed point σ_i we have that $\vDash_v (p \leftrightarrow \gamma_i)$, and thus, since v was chosen arbitrarily we have that $\vDash_w \Box(p \leftrightarrow \gamma_i)$. So by using 6.1 again we get that $\vDash_v \boxdot(p \leftrightarrow \gamma_i)$. We will now use lemma 6.3 again and get that:

<div style="text-align: left">{eqn:sub1}</div>

$$\vDash_v \gamma_i(p) \leftrightarrow \gamma_i(\sigma_i) \tag{6.2}$$

and

<div style="text-align: left">{eqn:sub2}</div>

$$\vDash_v \Box\gamma_i(p) \leftrightarrow \Box\gamma_i(\sigma_i) \tag{6.3}$$

Notice that these two holds for any $v \in \{w\} \cup \mathrm{acc}(w)$ such that $\vDash_v \Box\gamma_i(p)$. Further by 6.3 we can deduce $\vDash_v \Box\gamma_i(p) \rightarrow \Box\gamma_i(\sigma_i)$

For the next step of the prove of this lemma we will assume that $\nvDash_v \Box\gamma_i(p)$. This means by lemma 6.2 that there is some world v' where $v' \in \mathrm{acc}(v)$, such that $\nvDash_{v'} \gamma_i(p)$ and $\vDash_{v'} \Box\gamma_i(p)$. 6.2 holds for v' since $v' \in \{w\} \cup \mathrm{acc}(w)$ and thus we have $\vDash_{v'} \gamma_i(p) \leftrightarrow \gamma_i(\sigma_i)$. This gives that $\nvDash_{v'} \gamma_i(\sigma_i)$ and thus since vRv' we have that $\nvDash_v \Box\gamma_i(\sigma_i)$. By contraposition we then get: $\vDash_v \Box\gamma_i(\sigma_i) \rightarrow \Box\gamma_i(p)$, and thus we have shown that:

$$\vDash_v \Box\gamma_i(p) \leftrightarrow \Box\gamma_i(\sigma_i)$$

We have now shown the lemma. ⊣

We now go back and finish our proof of the fixed point theorem. Suppose that $\mathcal{K}$ is a model and that $w \in W$ such that $\vDash_w \boxdot (p \leftrightarrow \alpha)$. By lemma 6.4 and completeness we get $\vDash_w \boxdot(\Box\gamma_i(p) \leftrightarrow \Box\gamma_i(\sigma_i))$. By using lemma 6.3 $(n+1)$ times we can deduce that:

$$\vDash_w \beta(\Box\gamma_i(p), \ldots, \Box\gamma_{n+1}(p)) \leftrightarrow \beta(\Box\gamma_1(\sigma_1), \ldots, \Box\gamma_{n+1}(\sigma_{n+1}))$$

i.e $\vDash_w \alpha \leftrightarrow \sigma$.

Since we have $\vDash_w p \leftrightarrow \alpha$ we get $\vDash_w p \leftrightarrow \sigma$, we can obtain $\vDash_w \boxdot(p \leftrightarrow \alpha) \rightarrow (p \leftrightarrow \sigma)$. Since our $\mathcal{K}$ and w was chosen at random we have that $\boxdot(p \leftrightarrow \alpha) \rightarrow (p \leftrightarrow \sigma)$ is valid. By completeness we then have: $\vdash_{\mathbf{GL}} \boxdot(p \leftrightarrow \alpha) \rightarrow (p \leftrightarrow \sigma)$ ⊣

The following result follows from the fixed-point theorem.

Theorem 6.2 Let $\alpha(p)$ be modalized in p, and let σ be a fixed-point of α. Then:

$$\vdash_{\mathbf{GL}}\boxdot(p \leftrightarrow \sigma) \to (p \leftrightarrow \alpha)$$

Proof. Suppose that $\mathcal{K} = \langle W, R, \phi \rangle$ is a finite transitive and irreflexive model in which $\boxdot(p \leftrightarrow \sigma) \to (p \leftrightarrow \alpha)$ is invalid. This means that for some $w \in W$ of least rank that we have: $\vDash_w\boxdot(p \leftrightarrow \sigma)$ and thus $\vDash_w p \leftrightarrow \sigma$ and $\nvDash_w p \leftrightarrow \alpha$. If wRv then $\vDash_v\boxdot(p \leftrightarrow \sigma)$ and since x of lower rank than w we also have $\vDash_v p \leftrightarrow \alpha$. Let φ' be like φ expect that $p \in \phi'(w)$ if and only if not $p \in \phi(w)$. Set $\mathcal{K}' = \langle W, R, \phi' \rangle$, and this model is clearly transitive and irreflexive.

In the rest of this prove we will use corollary to the continuity theorem; i.e corollary 5.3.

The formula α is a truth-functional compound of closed formulas $\Box\beta$ and proportional letters q such that each q is not p. We have that $\vDash_w^{\mathcal{K}} \Box\beta$ if and only if $\vDash_v^{\mathcal{K}} \beta$ for all v such that wRv, if and only if $\vDash_v^{\mathcal{K}'}$ for all v such that wRv (by continuity), if and only if $\vDash_w^{\mathcal{K}'} \Box\beta$. We further have by the definition of $\mathcal{K}'$ that $\vDash_w^{\mathcal{K}} \alpha$ if and only iff $\vDash_w^{\mathcal{K}'}$ and $\vDash_w^{\mathcal{K}} p$ if and only if not $\vDash_w^{\mathcal{K}'} p$. Thus we have $\vDash_w^{\mathcal{K}'} p \leftrightarrow \alpha$ and b the continuity theorem we again get $\vDash_v^{\mathcal{K}'} p \leftrightarrow \alpha$ for all v such that wRv. But this means that we get $\vDash_w^{\mathcal{K}'}\boxdot(p \leftrightarrow \alpha)$.

Since σ does not contain p we get by the conti them that $\vDash_w^{\mathcal{K}} \sigma$ if and only if $\vDash_w^{\mathcal{K}'} \sigma$. Since we have that $\vDash_w^{\mathcal{K}} p$ if and only if not $\vDash_w^{\mathcal{K}'} p$ we get $\nvDash_w^{\mathcal{K}'} p \leftrightarrow \sigma$ and thus $\boxdot(p \leftrightarrow \sigma) \to (p \leftrightarrow \sigma)$ is invalid.

By soundness and completeness of **GL** we thus get that if $\vdash_{\mathbf{GL}}\boxdot(p \leftrightarrow \alpha) \to (p \leftrightarrow \sigma)$ then $\vdash_{\mathbf{GL}}\boxdot(p \leftrightarrow \sigma) \to (p \leftrightarrow \alpha)$. $\dashv$

From this we can prove the following corollary that show that the name fixed-point is appropriate:

Corollary 6.1 Let $\alpha(p)$ be modalized in p and let σ be a fixed-point of α. Then:

$$\vdash_G \sigma \leftrightarrow \alpha(\sigma)$$

Proof. Since we have assumed uniform substitution and by theorem 6.2 the result of substituting σ for p in $\boxdot(p \leftrightarrow \sigma) \to (p \leftrightarrow \alpha)$ is a theorem of **GL**. This means that $\vdash_{\mathbf{GL}}\boxdot(\sigma \leftrightarrow \sigma) \to (\sigma \leftrightarrow \alpha(\sigma))$. $\boxdot(\sigma \leftrightarrow \sigma)$ is obviously a theorem of **GL** so we get:

$$\vdash_{\mathbf{GL}} \sigma \leftrightarrow \alpha(\sigma)$$

$\dashv$

We can also state (by theorem 6.2 and 6.1)the fixed point theorem in the following form:

Corollary 6.2 For every modal formula α modalized in p, there is a modal formula σ only contaning propostional letters contained in α not contaning p such that:

$$\vdash_{\mathbf{GL}}\boxdot(p \leftrightarrow \alpha) \leftrightarrow \boxdot(p \leftrightarrow \sigma)$$

With the fixed theorem a lot of different fixed points can be calculated. The formula on the left is the formula $\alpha(p)$ and the formula on the right is the formula σ.

1. $\neg\Box p$	$\neg\Box\bot$
2. $\Box p$	$\top$
3. $\Box\neg p$	$\Box\bot$
4. $\neg\Box\neg p$	$\neg\Box\bot$
5. $\neg\Box\Box\neg p$	$\neg\Box\Box\bot$
6. $\Box p \to \Box\neg p$	$\Box\Box\bot \to \Box\bot$
7. $\Box(\neg p \to \Box\bot) \to \Box(p \to \Box\bot)$	$\Box\Box\Box\bot \to \Box\Box\bot$
8. $\Box p \to q$	$\Box q \to q$
9. $\Box(p \to q)$	$\Box q$
10. $\Box p \wedge q$	$\Box q \wedge q$
11. $\Box(p \wedge q)$	$\Box q \wedge q$
12. $q \vee \Box p$	$\top$
13. $\neg\Box(q \to p)$	$\Diamond q$
14. $\Box(p \to q) \to \Box\neg p$	$\Box(\Box\bot \to q) \to \Box\bot$
15. $q \wedge (\Box(p \to q) \to \Box\neg p)$	$q \wedge \Box\neg q$
16. $\Diamond p \to (q \wedge \neg\Box(p \to q))$	$\Diamond\top \to (q \wedge \neg\Box(\Box\bot \to q))$
17. $\Box(\Box(p \wedge q) \wedge \Box(p \wedge r))$	$\Box(\Box q \wedge \Box r)$

Figure 6.1: A Table of Fixed Points

We will after the proof of Solovay's Completeness Theorems come back to this table, and make some conclusions about the fixed points.

7 Solovays Completeness Theorems

In this section we will prove Solovay's completeness theorems. The proof of these theorems follows a technique invented by Robert Solovay, which today is known as a *Solovay construction*. This technique is a way of embedding Kripke models into arithmetic. The first theorem show that the $\square$-operator of the logic **GL** behaves like the proof predicate Pr from **PRA**. The second theorem shows that the modal logic **GLS**.

Further these theorems shows that the proof predicate of arithmetics can be axiomatized, by the axioms of **GL** and **GLS**.

7.1 Soundness

For each formula in $\mathcal{L}_\square$ we want to assign a sentence of $\mathcal{L}_{\textbf{PRA}}$. This can be done in the following way.

Definition 7.1 An interpretation of $\mathcal{L}_\square$ in **PRA** is a function that to each formula α of $\mathcal{L}_\square$ assigns a sentence α^* of **PRA** which satisfies the following requirements:

1. For atomic p, p^* is a formula of the language of arithmetic

2. $(\bot)^* = "0 = 1"$

3. $(\alpha \to \beta)^* = "\alpha^* \to \beta^*"$

4. $(\square\alpha)^* = "\Pr(\ulcorner \alpha^* \urcorner)"$

We will further say that a modal formula α is **PRA**-valid if, in every interpretation *, α^* is a theorem of **PRA**. $\dashv$

The goal of the current section is to prove the that the set of **PRA**-valid formulas are the theorems of **GL**. I.e we want to prove the following bi-implication:

$$\textbf{GL} \vdash \alpha \Leftrightarrow \forall^*(\textbf{PRA} \vdash \alpha^*)$$

This formula says that **GL** completely captures what **PRA** can say about its own provability. This result can be expanded to other fragments of arithmetics. So the modal logic **GL** is the modal logic that captures what a lot of different fragments

of arithmetics can say about its own provability. Later on in the project it will be shown for which fragments this is the case.

In 7.3 we will show that **GLS** is the modal logic of provability in truth. This is called Solovay's second completeness theorem.

We will start with proving the "⇒" implication; i.e that every theorem of **GL** is **PRA**-valid. The other way will be a bit harder to prove, and that is the part that is known as Solovay's first completeness theorem.

Theorem 7.1 (Soundness) For all modal sentences φ we have that :

$$\mathbf{GL} \vdash \varphi \Rightarrow \forall^*(\mathbf{PRA} \vdash \varphi^*)$$

Proof. The proof will be done as an induction proof on the number of axioms and rules of inference use in a **GL**-proof of a formula α. The proof will be done by looking at the last rule or axiom schema used in the proof of α.

The case of A1 and R1 are clear. We further have that the theorems of **PRA** are closed under modus ponens so A2 is also clear.

Assume that the last step of the proof of α is an instance of R2. We have that $\Pr(x)$ is Σ_1 formula, so it is equivalent to some formula of the form $\exists y R(x, y)$, where R is a primitive recursive predicate. We know that if a Σ_1 sentences is true it is provably, so this shows the case of R2.

The axiom A3 can be derived from the others, so this case is redudant.

We will now just have to show the case of A4. This case follows by Löb's theorem. ⊣

7.2 The First Theorem

Having shown soundness, we will now show the completeness theorem:

Theorem 7.2 (Solovay's first completeness theorem) For all modal sentences φ we have that:
$$\forall^*(\mathbf{PRA} \vdash \alpha^*) \Rightarrow \mathbf{GL} \vdash \alpha$$

This theorem will be shown by contraposition. So we want to show the following: "If **GL** $\nvdash \alpha$ then we have one * such that **PRA** $\nvdash \alpha^*$". The start of the proof is the following: If **GL** $\nvdash \alpha$ then **GL** $\nvdash \alpha$ and thus there is a finite pointed Kripke model $\mathcal{K} = \langle W, R, \phi, w_0 \rangle$ in which we have $w_0 \notin \phi(\alpha)$. The goal is then to find an interpretation * such that **PRA** $\nvdash \alpha^*$.

The construction of this * is rather complex, and will take the rest of this subsection to prove. So for the rest of this subsection fix a sentence φ such that **GL** $\nvdash \varphi$ and let $\mathcal{K} = \langle W, R, \phi, w_0 \rangle$ be a pointed Kripke model such that $w_0 \in \phi(\alpha)$.

We will assume without loss of generality that $W = \{0, \ldots, n\}$ for some finite n and that $w_0 = 1$. R can be extended by setting $0Ri$ for each i in W. Is shall be noted that 0 is not part of our Kripke model, but we will in section refchap:second create a model where it is a part of the model.

Further we will first intuitively define a function $\varphi : \omega \to \{0, \ldots, n\}$ in the following way: Set $\varphi(0) = 0$. Further we define $\varphi(x + 1)$ in the following way: If $x + 1$ is the code of a proof that $\lim_{k \to \infty}(k) \neq z$ for some z accessible to $\varphi(x)$ we set $\varphi(x + 1) = z$ otherwise we have that $\varphi(x + 1) = \varphi(x)$.

The way this function works can be explained intuitively by the following quote:

> Imagine a refugee who is admitted from one country to another only if he/she provides a proof not to stay there forever. If the refugee is also never allowed to go to one of the previously visited countries, he/she must eventually stop somewhere. So, an honest refugee will never be able to leave his/her country of origin. [Beklemeishev og artemov, find biktex reference]

Before we can give a formal definition of the function φ, we will have to introduce some notation. First of we will let ψ be an arbitrary partial recursive function with the following Σ_1 graph: $\tau v_0 v_1$. From this graph we can obtain the following Σ_2 formula:

$$\exists v_0 \forall v_1 > v_0 : \tau v_1 v$$

Which says that ψ has limit v. We will abbreviate this as $L_\psi = v$. We will use this notation to define φ in the following way:

$$\varphi(v_0) = v_1 \leftrightarrow \begin{cases} (v_0 = \overline{0} \wedge v_1 = \overline{0}) \vee \\ (v_0 > \overline{0} \wedge Prov(v_0, \ulcorner L \neq \dot{v}_1 \urcorner) \wedge \varphi(v_0 \dot{-} \overline{1})\overline{R}v_2) \vee \\ (v_0 > \overline{0} \wedge \forall v_2 \leq v_0 \neg (Prov(v_0, \ulcorner L \neq v_2 \urcorner) \wedge \overline{\varphi}(v_0 \dot{-} \overline{1})\overline{R}v_2 \wedge \\ v_1 = \overline{\varphi}(v_0 - \overline{1})) \end{cases}$$

We will define the graph $\tau v_0 v_1 = \exists v_3 \chi v_3 v_0 v_1$ of the partial recursive function φ. Since we have that the graph of φ is Σ_1 we have that the graph τ is also Σ_1 and thus the graph χ is Δ_0. We will define a formula $\Phi(\chi)$ as the disjunction of the following three formulas:

1. $v_0 = \overline{0} \wedge v_1 = \overline{0}$

2. $v_0 > \overline{0} \wedge \mathrm{Prov}(v_0, \ulcorner L_\tau \neq v_1 \urcorner) \wedge \exists v_4(\tau(v_0 \dot{-} \overline{1}, v_4) \wedge v_4 \overline{R} v_1)$

3. $v_0 > \overline{0} \wedge \exists v_3 v_4 \forall v_2 \leq v_0 \neq (\mathrm{Prov}(v_0, \ulcorner L_\tau \neq v_2 \urcorner) \wedge \chi(v_3, v_0 - \overline{1}, v_4) \wedge v_4 \overline{R} v_1)$
   $\wedge \tau(v_0 - \overline{1}, v_1)$

Thus we have that the set $\Phi(\chi)$ can be seen as a primitive recursive function of $\ulcorner\chi\urcorner$; i.e we have:

$$\ulcorner\Phi(\chi)\urcorner = \vartheta(\ulcorner\chi\urcorner)$$

Since primitive functions are recursive we have by the Recursion Theorem that we can pick an n such that $\varphi_{\vartheta(n)} = \varphi_n$. Now set $\varphi = \varphi_n$. This definition of φ is rather involved. But we have defined φ by its own graph, and avoided the imperant circularity by using the recursion theorem to not rely on the graph.

We further define the relation $\overline{R}$ by listing all pairs $(x,y) \in R$ (We can do this since the set R is finite) and then define:

$$v_0\overline{R}v_1 : \bigvee_{(x,y)\in R} (v_0 = \overline{x} \wedge v_1 = \overline{y})$$

Thus we have that φ have the following properties:

1. $\varphi(0) = 0$

2. If $x+1$ proves that $L \neq \overline{z}$ and we have that $\varphi(x)Rz$, then $\varphi(x+1) = z$

3. Else we have that $\varphi(x+1) = \varphi(x)$

Further it is a total function since it is defined by recursion, and this can be proven in **PRA**.

Proposition 7.1 Let ψ be the Σ_1-formula that defines the graph of φ. Then:

$$\mathbf{PRA} \vdash \forall v_0 \exists! v_1 \psi v_0 v_1$$

Proof. The uniqueness of v_1 is given by the definition of φ. The existence of a value is given by induction on v_0 in the Σ_1 formula $\exists v_1 \psi v_0 v_1$ in **PRA**, and thus this induction is possible in **PRA**.

Base step: When $v_0 = 0$ we have that $\psi(0) = 0$ by definition of φ; i.e $\exists v_1 \psi v_0 v_1$, where $v_1 = 0$.

Induction step: Assume that $\exists v_1 \psi v_0 v_1$ holds for $v_0 = n$, i.e we have a $v_1 = m$ such that $\varphi(n) = m$. Look at $\varphi(n+1)$, then if $n+1$ proves that $L_\psi \neq \overline{z}$ and we have that $\varphi(n)Rz$, then we will have that $\varphi(n+1) = z$, i.e $v_1 = z$ otherwise we will have that $\varphi(n+1) = \varphi(n) = m$, and the induction is done. $\dashv$

Further we will expand the langauge with a new function constant (This can be done, since ψ is the graph of a total function) $\overline{\varphi}$ with the following defining axiom:

$$\overline{\varphi}(v_0) = v_1 \leftrightarrow \psi(v_0) = v_1$$

We will now prove and state a few lemmas about the function φ and the limit of this function $L\tau = L$. These will build up the proof of Solovay's First Completeness Theorem. Thus we will use the function φ and the limit L to deduce the theorem

{lem:2}

Lemma 7.1 The following three statements holds:

1. $\mathbf{PRA} \vdash \forall v_0(\overline{\varphi}v_0 \leq \overline{n})$

2. For all $x \in \omega$ we have that:

$$\mathbf{PRA} \vdash \forall v_o(\overline{\varphi}v_0 = \overline{x} \to \forall v_1 > v_0(\overline{\varphi}v_1 = \overline{x} \vee \overline{x}\overline{R\varphi}v_1))$$

3. $\mathbf{PRA} \vdash \exists v_0 v_1 \forall v_2 > v_0(\overline{\varphi}v_2 = v_1)$.

Where (3) just means that $\mathbf{PRA} \vdash \exists v_1(L = v_1)$.

Proof. We will prove each part separately

1. We will prove this part by induction.

   Base case: $\varphi(0) = 0 \leq n$ is is clearly true.

   Induction step: Assume that $\varphi(x) \leq n$ is true. Then we have that $\varphi(x+1)$ is in the range of φ and this $\leq n$ or we have that $\varphi(x + 1) \leq n$ so the induction is complete.

2. We will start of by write the formula we have to prove as the following equivalent formula:

   $$\forall v_1 \forall v_0(\overline{\varphi}v_0 = \overline{x} \to \varphi(v_0 + v_1 + \overline{1}) = \overline{x} \vee \overline{x}\overline{R\varphi}(v_0 + v_1 + 1))$$

   To prove this we will use induction on v_1. This is an induction on a Π_1 formula; which is a possible induction for $\mathbf{PRA}$ by [Ref]

   Base case: if $v_1 = 0$ then clearly we have that $\varphi(v_0 + 1) = \overline{x}$ or $\overline{x}\overline{R\varphi}(v_0 + 1)$ by the definition of φ.

   Induction step: Assume that it holds for $v_1 = n - 1$, i.e that we for all v_0 have that:
   $$\varphi(v_0 + \overline{n}) = \overline{x} \text{ or } \overline{x}\overline{R\varphi}(v_0 + \overline{n})$$

   We will split the rest of this proof up in two parts; one where the first disjunct is true, and one where the second is true.

   The first disjunct is true:. Assume that both $v_0 + n + 1$ codes a proof that $L \neq z$ and $\varphi(v_0 + \overline{n})Rz$ is true. This means that $\varphi(v_0 + \overline{n} + 1) = z$. But this is just that $x\overline{R}\varphi(v_0 + \overline{n} + 1)$, and the lemma is true in this case. If these

assumptions are not true, we will then have that $\varphi(v_0 + \overline{n} + 1) = \varphi(v_0 + \overline{n})$. But then we have that $\varphi(v_0 + \overline{n} + 1) = \overline{x}$, and the lemma holds.

The second disjunct is true: We will again start of by assuming that $L \neq z$ and $\varphi(v_0 + n)Rz$; i.e $\varphi(v_0 + n + 1) = z$. We then get that $\varphi(v_0 + n)R\varphi(v_0 + n + 1)$ and by the transitivity of R we get: $x\overline{R}\varphi(v_0 + n + 1)$. If we otherwise have that $\varphi(v_0 + n) = \varphi(v_0 + n + 1)$ we clearly have that $\overline{x}\overline{R}\varphi(v_0 + n + 1)$.

3. Here we will first prove the following:

$$\forall v_0 (\exists v_1 (\overline{F}v_1 = v_0) \rightarrow \exists v_1 (L = v_1))$$

This is clearly true for $v_0 > n$. For $v_0 \leq n$ we will use induction on the converse of R. By 2) from this lemma it holds for maximal nodes y in W. If y is not a maximal note and $\exists v_1 (\overline{\varphi}(v_1) = \overline{x})$ then again by 2) we either get that $L = \overline{x}$ or that for some y such that xRy: $\exists v_1 (\overline{\varphi}(v_1) = \overline{y})$, and the induction hypothesis gives us that $\exists v_1 (L = v_1)$. But since the set W is finite we will end up with getting:

$$\mathbf{PRA} \vdash \exists v_1 (\overline{\varphi}(v_1) = \overline{0}) \rightarrow \exists v_1 (L = v_1)$$

But we have that $\mathbf{PRA} \vdash \overline{\varphi}(\overline{0}) = \overline{0}$ so clearly: $\mathbf{PRA} \vdash \exists v_1 (L = v_1)$

$\dashv$

Kommenter på Inductionen brugt ovenover.

Corollary 7.1 $\mathbf{PRA} \vdash L \leq \overline{n}$, i.e $\mathbf{PRA} \vdash \bigvee_{x \leq n} L = \overline{x}$

Proof. By lemma 7.1 1) and 3) and the following implication:

$$\mathbf{PRA} \vdash v \leq \overline{n} \rightarrow \bigvee_{x \leq n} v = \overline{x}$$

The corollary follows. $\dashv$

{lem:4}

Lemma 7.2 For all $x, y \leq n$ we have that:

1. $L = \overline{x} \wedge \overline{x}\overline{R}\overline{y} \rightarrow \mathrm{Con}_{\mathbf{PRA}+L=\overline{y}}$

2. $\mathbf{PRA} \vdash L = \overline{x} \wedge \overline{x} \neq \overline{y} \wedge \neg(\overline{x}\overline{R}\overline{y}) \rightarrow \neg\mathrm{Con}_{\mathbf{PRA}+L=\overline{y}}$

3. $\mathbf{PRA} \vdash L = \overline{x} \wedge \overline{x} > \overline{0} \rightarrow \mathrm{Pr}(\ulcorner L \neq \overline{x} \urcorner)$

Proof. We will prove each statement separately:

1) Let xRy and assume for contradiction that $L = \overline{x} \wedge \Pr(\ulcorner L \neq \overline{y} \urcorner)$. Since we have that $L = \overline{x}$ we can chose a v_0 such that $\forall v_2(v_2 > v_0 \to \overline{F}v_2 = \overline{x})$ and we can also chose $v_1 + \overline{1} > v_0$ such that $\mathrm{Prov}(v_1 + \overline{1}, \ulcorner L \neq \overline{y} \urcorner)$ But we also have the following:

$$\mathbf{PRA} \vdash \mathrm{Prov}(v_1 + \overline{1}, \ulcorner L \neq y \urcorner) \wedge \overline{F}v_1 = \overline{x_1, \dots, x_n} \wedge \overline{x}\overline{R}\overline{y} \to \overline{F}(v_1 + \overline{1}) = \overline{y}$$

This contradicts with $\forall v_2 > v_0(\overline{F}v_0 = \overline{x})$ which came from the assumption that $L = \overline{x}$ so we con conclude:

$$\mathbf{PRA} \vdash L = \overline{x} \wedge \overline{x}\overline{R}\overline{y} \to \neg\Pr(\ulcorner L \neq \overline{y} \urcorner)$$

Where we have that $\neg\Pr(L \neq \overline{y})$ is equivalent to $\mathrm{Con}_{\mathbf{PRA}+L=\overline{y}}$ and 1) follows.

2) By [ref???] We have the following deduction:

$$\mathbf{PRA} \vdash L = \overline{x} \to \exists v_0(\overline{F}v_0 = \overline{x}) \tag{7.1}$$

$$\to \Pr(\ulcorner \exists v_0(\overline{F}v_0 = \overline{x}) \urcorner) \tag{7.2} \quad \texttt{\{eq:21\}}$$

Further we have from lemma 7.1.2 and [D2, lob?] that:

$$\mathbf{PRA} \vdash \forall v_0(\overline{F}v_0 = \overline{x} \to (L = \overline{x} \vee \overline{x}\overline{R}L)) \tag{7.3}$$

$$\mathbf{PRA} \vdash (\ulcorner \forall v_0(\overline{F}v_0 = \overline{x} \to (L = \overline{x} \vee \overline{x}\overline{R}L)) \urcorner) \tag{7.4} \quad \texttt{\{eq:22\}}$$

From 7.2 and 7.4 we have the following:

$$\mathbf{PRA} \vdash L = \overline{x} \to \Pr(\ulcorner L = \overline{x} \vee \overline{x}\overline{R}L \urcorner) \tag{7.5} \quad \texttt{\{eq:23\}}$$

asd?

Which gives us [Why?]

$$\mathbf{PRA} \vdash \overline{x} \neq \overline{y} \wedge \neg(\overline{x}\overline{R}\overline{y}) \to \Pr(\ulcorner x \neq y \wedge \neg(\overline{x}\overline{R}\overline{y}) \urcorner)$$

This with 7.5 gives us:

$$\mathbf{PRA} \vdash L = \overline{x} \wedge \overline{x} \neq \overline{y} \wedge \neg\overline{x}\overline{R}\overline{y} \to \Pr(\ulcorner L = \overline{x} \vee \overline{x}\overline{R}L \urcorner) \wedge \Pr(\ulcorner x \neq \overline{y} \wedge \neg\overline{x}\overline{R}\overline{y} \urcorner)$$

From which we can deduce:

$$\mathbf{PRA} \vdash L\overline{x} \wedge \overline{x} \neq \overline{y} \wedge \neg\overline{x}\overline{R}\overline{y} \to \Pr(\ulcorner L \neq \overline{y} \urcorner)$$

Which gives us 2)

3) From the least number princible we have that:

$$\mathbf{PRA} \vdash L = \overline{x} \wedge \overline{x} > \overline{0} \rightarrow \exists v(\overline{F}(v + \overline{1}) = \overline{x} \wedge \overline{F}v \neq \overline{x})$$

By the definition of F we have for such a v the following:

$$\mathbf{PRA} \vdash \overline{F}(v + \overline{1}) = \overline{x}\overline{F}v \neq \overline{x} \rightarrow \mathrm{Prov}(v + \overline{1}, \ulcorner L \neq \overline{x} \urcorner)$$

And thus we have the following:

$$\mathbf{PRA} \vdash L = \overline{x} \wedge \overline{x} > \overline{0} \rightarrow \mathrm{Pr}(\ulcorner L \neq \overline{x} \urcorner)$$

$$\dashv$$

Lemma 7.1 and 7.2 gives us the moss of the facts that we need about L and φ; at least the facts about them that we can prove in **PRA**. We will also need the following result, which cannot be proven in **PRA**.

{lem:5}

Lemma 7.3 The following two statements are true, but they cannot be proven in **PRA**.

1. $L = \overline{0}$

2. For $0 \leq x \leq n$ we have that $\mathbf{PRA} + L = \overline{x}$ is consistent.

Proof. **1)** By lemma 7.1.3 the limit L exists. If $x > 0$ we have by lemma 7.2 that:

$$L = \overline{x} \Rightarrow \mathbf{PRA} \vdash L \neq \overline{x}$$
$$\Rightarrow L \neq \overline{x}$$

Since **PRA** is sound. But this is a contradiction and we must conclude that $L = 0$.

2) Since we have that $L = \overline{0}$ is true and we have that **PRA** is sound, we have that $\mathbf{PRA} + L = \overline{0}$ is consistent. For $x > 0$ we will apply lemma 7.2.1 and get:

$$\mathbf{PRA} \vdash L = \overline{0} \wedge \overline{0}R\overline{x} \rightarrow \mathrm{Con}_{\mathbf{PRA} + L = \overline{x}}$$

We have that the antecedent is true and hence that $\mathrm{Con}_{PRA+L=\overline{x}}$ is true, which proves this part of the lemma. $\dashv$

We have now shown all the important basic properties that φ and L holds. In the next part of the proof we will simulate the Kripke model $\mathcal{K} = \langle W, R, \phi \rangle$, where $1 \notin \phi(\alpha)$. For this end we will let $L = \overline{x}$, for $x > 0$, assume the rule nodes of $W = \{1, \ldots n\}$. We will start of by defining the interpretation *. So for any p let:

$$p^* = \bigvee \{L = \overline{x} : 1 \leq x \leq n \text{ and } x \in \phi(p)\}$$

If this disjunction is empty, we will set it to be $\overline{0} = \overline{1}$. Further we are only interested the sentence α; i.e the set:

$$S(\alpha) = \{\beta : \ \beta \text{ is a subformula of } \ \alpha\}$$

We will not look at $p \notin S(\alpha)$

The following lemma is the crucial result about this interpretation, and the theorem will follow easily from this result:

{lem:10}

Lemma 7.4 Let $1 \le x \le n$. For any β and * as defined just above we have that:

1. $x \in \phi(\beta) \Rightarrow \mathbf{PRA} \vdash L = \overline{x} \to \beta^*$

2. $x \notin \phi(\beta) \Rightarrow \mathbf{PRA} \vdash L = \overline{x} \to \neg\beta^*$

Proof. We will use induction on complexity of ψ. If $\beta = p$, then since $L = \overline{x}$ is a disjunct of p^* we get:

$$x \in \phi(\varphi) \Rightarrow \mathbf{PRA} \vdash L = \overline{x} \to p^*$$

Which proves 1, for ψ atomic. For 2 observe that if $x \notin \phi(p)$, then $L = \overline{x}$ contradicts all the disjuncts of p^* and thus:

$$x \notin \phi(p) \to \mathbf{PRA} \vdash L = \overline{x} \to \neg p^*$$

The cases where ψ is $\neg\gamma, \gamma \wedge \sigma, \gamma \vee \sigma$ and $\gamma \to \sigma$ are trivial. So we will just look at the case where $\psi = \Box\gamma$. Here we make the following deductions:

$$
\begin{aligned}
x \in \phi(\Box\theta) &\Rightarrow \forall y(xRy \Rightarrow y \in \phi(\gamma)) \\
&\Rightarrow \forall(xR \Rightarrow \mathbf{PRA} \vdash L = \overline{y} \to \gamma^*) \\
&\Rightarrow \bigwedge_{xRy}(\mathbf{PRA} \vdash L = \overline{y} \to \gamma^*) \\
&\Rightarrow \mathbf{PRA} \vdash \bigvee_{xRy} L = \overline{y} \to \gamma^* \\
&\Rightarrow \mathbf{PRA} \vdash \Pr(\ulcorner\textstyle\bigvee_{xRy} L = \overline{y}\urcorner) \to \Pr(\ulcorner\gamma^*\urcorner)
\end{aligned}
$$

And by the last line we can get the following by using the axioms of **GL**

$$x \in \phi(\Box\gamma) \Rightarrow \mathbf{PRA} \vdash \Pr(\ulcorner\textstyle\bigvee_{xRy} L = \overline{y}\urcorner) \to \Pr(\ulcorner\gamma^*\urcorner) \tag{7.6}$$ {eq:1}

We can now invoke lemma 7.3 2 and 3 and get:

$$\mathbf{PRA} \vdash L = \overline{x} \to \bigwedge_{\neg(xRz)} \Pr(\ulcorner L \neq z\urcorner) \tag{7.7}$$ {eq:2}

and therfore we have that:

$$\mathbf{PRA} \vdash L = \overline{x} \to \Pr(\ulcorner \bigvee_{xRy} L = \overline{y} \urcorner) \tag{7.8} \quad \texttt{\{eq:3\}}$$

Now by 7.6 and 7.8 we get that:

$$\vdash_x \Box\theta \Rightarrow \mathbf{PRA} \vdash L = \overline{x} \to \Pr(\ulcorner \gamma^* \urcorner)$$
$$\Rightarrow \mathbf{PRA} \vdash L = \overline{x} \to (\Box\gamma)^*$$

I.e we have proven part 1 of the lemma. Similarly we can do the following deduction:

$$x \notin \phi(\Box\gamma) \Rightarrow \exists y(xRy \wedge y \notin \phi(\gamma))$$
$$\Rightarrow \exists y(xRy \wedge \mathbf{PRA} \vdash L = \overline{y} \to \neg\gamma^*)$$
$$\Rightarrow \exists y(xRy \wedge \mathbf{PRA} \vdash \gamma^* \to L \neq \overline{y})$$
$$\Rightarrow \exists y(xRy \wedge \mathbf{PRA} \vdash \Pr(\ulcorner \gamma^* \urcorner) \to \Pr(\ulcorner L \neq \overline{y} \urcorner))$$

But by lemma 7.3 we get that if xRy:

$$\mathbf{PRA} \vdash L = \overline{x} \to \neg\Pr(\ulcorner L \neq \overline{y} \urcorner)$$

all in all this gives us:

$$\mathbf{PRA} \vdash L = \overline{x} \to \neg\Pr(\ulcorner \gamma^* \urcorner)$$

Which is just just the following we where trying to show:

$$\mathbf{PRA} \vdash L = \overline{x} \to \neg(\Box\gamma)^*$$

$$\dashv$$

We can now finally prove Solovay's first completeness theorem:

Proof of Solovay's first completeness theorem. By lemma 7.4 we have that

$$1 \notin \phi(\alpha) \Rightarrow \mathbf{PRA} \vdash L = \overline{1} \to \neg\alpha^*$$

But by lemma 7.3 we have that $\mathbf{PRA} + L = 1$ is consistent, from which it follows that $\mathbf{PRA} + \neg\varphi^*$ is consistent; so φ^* is not a theorem af $\mathbf{PRA}$ and thus we have: $\mathbf{PRA} \nvdash \varphi^*$ and the theorem follows by contraposition. $\dashv$

With this proof we can give a interpretation of the set W and relation R in a model of $\mathbf{GL}$. The set W consists of recursively axiomitized extensions of $\mathbf{PRA}$.

And we have that $w_1 R w_2$ if and only if $w_1 \vdash \mathrm{Con}(w_2)$, i.e the theory w_1 has the consistency of theory w_2 as one of its theorems. It is clear that this relation is transitive and conversely well-founded.

7.3 The Second Theorem

{chap:second}

Solovay's Second Completeness Theorem is a strengthening of the first one, since it tells about trueness of a formuae α^* in the standard model $\mathcal{N} = \langle \omega, +, \cdot \rangle$ of aritmetics. The proof will follow that of the first theorem, but we will look at the modal logic **GLS** instead of the modal logic **GL**.

Theorem 7.3 For all modal sentences φ, the following is equivalent:

1. $\mathbf{GLS} \vdash \alpha$

2. $\mathbf{GL} \vdash \bigwedge_{\Box\beta \in S(\alpha)} (\Box\beta \to \beta) \to \alpha$

3. α is true in all α-sound Kripke models

4. $\forall^*(\alpha^*$ is true$)$

Some parts of this theorem has already been proven. We have (1) $\Leftrightarrow$ (2) by theorem [asd?] and we have (2) $\Leftrightarrow$ (3) by theorem [asd?]. **Udbyd dette senere**

For proving (4) $\Rightarrow$ (3) we will again make use of contraposition. Let $\mathcal{K} = \langle (1, \ldots, n), R, \phi \rangle$ be given and let 1 be the root. Further let α be such that $1 \notin \phi(\alpha))$. We will assume that $\mathcal{K}$ is α-sound. This means that we have: $1 \in \phi(\Box\beta \to \beta)$ for all $\beta \in S(\alpha)$

We will set $0Rw$ for all $w \in W$. We will now create a new model $\mathcal{K}'$ where we have added 0, so in this proof it is part of the Kripke model we will look at. We will create this new model in the following way:

$W' = \{0, 1 \ldots, n\}$
R' extends R by assuming that $0R'x$ for all $x \in W$
$\alpha_0 = 0$
ϕ' extends ϕ by putting $0 \in \phi'(p)$ iff $1 \in \phi(p)$ for all $p \in S(\varphi)$

We will abuse notation and let R denote R' and ϕ denote ϕ'.

Lemma 7.5 For all $\beta \in S(\alpha)$ we have that:

$$0 \in \phi(\beta) \text{ iff } 1 \in \phi(\beta)$$

Proof. Kig på intro af GLS. ⊣

We will now define a function *varphi* in the same way as before.

$$\varphi(0) = 0$$

$$\varphi(x+1) = \begin{cases} y & \text{Prov}(\overline{x} + \overline{1}, \ulcorner L \neq \overline{y} \urcorner) \wedge xRy \\ \varphi(x) & \text{else} \end{cases}$$

All the Lemmas about φ and L still holds, since the function φ is only determined by the frame $\langle W, R \rangle$ and not the Kripke model that we are looking at. But the behavior of ϕ has changed, since we must added the node 0 and we can only use sub formulas of α. So we define:

$$p^* = \bigvee \{L = \overline{x} : 0 \leq x \leq n \wedge x \in \phi(p)\}$$

For $p \in S(\alpha)$ and let p^* be random for all p's that is not a subformula of α. We now prove and state the following lemma is analogies to lemma 7.3:

Lemma 7.6 Let $0 \leq x \leq n$. For any $\beta \in S(\alpha)$ and * as defined above we have:

1. $x \in \phi(\beta) \Rightarrow \mathbf{PRA} \vdash L = \overline{x} \to \beta^*$

2. $x \notin \phi(\beta) \Rightarrow \mathbf{PRA} \vdash L = \overline{x} \to \neg\beta^*$

Proof. For $0 < x$ the proof is identical to the proof of [ref?]. So we will only prove the case where $x = 0$. The is again an induction on the complexity of β. We will only prove the cases where $\beta = \Box\gamma$.

Let $\beta = \Box\gamma$. We then have:

$$0 \in \phi(\Box\gamma) \Rightarrow \forall x (1 \leq x \leq n \Rightarrow x \in \phi(\gamma))$$
$$\Rightarrow \forall x (1 \leq x \leq n \Rightarrow \mathbf{PRA} \vdash L = \overline{x} \to \gamma^*)$$

Since $x > 1$ and this case of the lemma has been proven, when we proved the lemma for the first completeness theorem. We can also make the following deduction by the induction hypothesis:

$$0 \in \phi(\Box\gamma) \Rightarrow 1 \in (\gamma)$$
$$\Rightarrow 0 \in \gamma)$$
$$\Rightarrow \mathbf{PRA} \vdash L = \overline{0} \to \gamma^*$$

By combing these two we get:

$$0 \in \phi(\Box\gamma) \Rightarrow \bigwedge_{x \leq n} (\mathbf{PRA} \vdash L = \overline{x} \to \gamma^*)$$

$$\Rightarrow \mathbf{PRA} \vdash (\bigvee_{x \leq n} L = \overline{x}) \to \gamma^*$$

$$= \mathbf{PRA} \vdash \Pr(\ulcorner \bigvee L = \overline{x} \urcorner) \to \Pr(\ulcorner \gamma^* \urcorner)$$

But by corollary [<ref?] we have that $\mathbf{PRA} \vdash \bigvee L = \overline{x}$ and thus $\mathbf{PRA} \vdash \Pr(\ulcorner \bigvee L = \overline{x} \urcorner)$ so all in all we have:

$$0 \in (\Box\gamma) \Rightarrow \mathbf{PRA} \vdash \Pr(\ulcorner \gamma^* \urcorner)$$

$$\Rightarrow \mathbf{PRA} \vdash L = \overline{0} \to \Pr(\ulcorner \gamma^* \urcorner)$$

This proves (1). The proof of (2) is a bit easier. We have:

$$0 \notin \phi(\Box\gamma) \Rightarrow \exists x(1 \leq x \leq n \wedge x \notin \phi(\gamma))$$

$$\Rightarrow \exists x(1 \leq x \leq n \wedge \mathbf{PRA} \vdash L = \overline{x} \to \neg\gamma^*)$$

$$\Rightarrow \exists x(1 \leq x \leq n \wedge \mathbf{PRA} \vdash \gamma^* \to L \neq \overline{x})$$

$$\Rightarrow \mathbf{PRA} \vdash L = \overline{0} \to \neg\Pr(\ulcorner \gamma^* \urcorner)$$

And thus by Lemma [Ref?] we have that $\mathbf{PRA} \vdash L = \overline{0} \to \neg\Pr(\ulcorner L \neq \overline{x} \urcorner)$ for $x > 0$ $\dashv$

We thus have that $L = \overline{0}$ is true, and we can now finally prove the second completeness theorem:

Proof of the Second Completeness theorem. Assume that α is false in $\mathcal{K}$ i.e $1 \notin \phi(\alpha)$. Then by lemma [asd] we get $0 \notin \phi(\alpha)$ and the just proven lemma gives:

$$\mathbf{PRA} \vdash L = \overline{0} \to \neg\alpha^*$$

Since we have that $L = \overline{0}$ is true we then get $\neg\alpha^*$ which just means that α^* is false. $\dashv$

7.3.1 Using the Second Completeness Theorem

We can use the second completeness theorem to prove the following theorem named after Rosser:

Theorem 7.4 There is a Σ_1-sentences φ such that:

1. $\mathbf{PRA} \nvdash \varphi$

2. $\mathbf{PRA} \nvdash \not\varphi$

3. $\mathbf{PRA} \vdash \mathrm{Con} \to \neg \Pr(\ulcorner \varphi \urcorner)$

4. $\mathbf{PRA} \vdash \mathrm{Con} \to \neg PPr(\ulcorner \neg \varphi \urcorner)$

7.4 Generalisations of the Completeness Theorems

In this section we have shown the Solovay's Completeness Theorems for **PRA**. But these theorems holds for a much wider class of fragments of Peano Arithmetics. It can be shown **REf De joghn** that the theorem holds for theories T that fulfills the following to conditions:

1. T extends $I\Delta_0 + \mathrm{EXP}$

2. Let $\alpha(x)$ be Δ_0 formula, then T does not prove any false sentences of the form $\exists x \alpha(x)$

This proof does not use the Recursion theorem for creating the function φ, but instead uses the diagonalization lemma (i.e Lemma 2.1). The proof of this will not this will not be given here, but it can be found in **Ref artiklen**.

It is not known if Solovays theorems holds for weaker conditions than $I\Delta_0 + \mathrm{EXP}$; i.e we do not know if it holds for example for the theory $I\Delta_0 + \Omega_1$.

Solovay's theorems can also be proven for some fragments without the use of fixed points. The two different proof strategies seen so fair each uses fixed points. Either by using the recursion theorem or by using the digitalization theorem for a given arithmetic theory. **Ref den russiske artikle**. This newer proof might be able to giver a specific lower bound on the strength of the fragments Solovays theorems holds for.

7.5 Solovays Completeness Theorems and Fixed Points

From table 6.1 we can conclude the following things:

1. From line 3, we have that $\vdash_{\mathbf{GL}} \boxdot(p \leftrightarrow \Box \neg p) \leftrightarrow \boxdot(p \leftrightarrow \Box \bot)$; i.e a sentence F of **PRA** is equivalent to its own unprovability if and only if F is equivalent to the assertion that **PRA** is inconsistent. For let $*$ be such that $F = p^*$, then we if F is such that $\mathbf{PRA} \vdash F \leftrightarrow \Pr(\ulcorner \neg F \urcorner)$ which is the same as $\mathbf{PRA} \vdash (p \leftrightarrow \Box \neg p)^*$ and thus we have: $\mathbf{PRA} \vdash \Box(p \leftrightarrow \Box \neg p)^*$ and hence $\mathbf{PRA} \vdash \boxdot(p \leftrightarrow \Box \neg p)^*$. But by Solovay's first completeness theorem we get

that: $\textbf{PRA} \vdash (\boxdot (p \leftrightarrow \Box \neg p) \leftrightarrow \boxdot (p \leftrightarrow \Box \bot))^*$, and thus $\textbf{PRA} \vdash \boxdot (p \leftrightarrow \Box \bot)^*$ whence $\textbf{PRA} \vdash (p \leftrightarrow \Box \bot)^*$ and thus $\textbf{PRA} \vdash F \leftrightarrow \mathrm{Pr}(\ulcorner \bot \urcorner)$. Which shows that F is equivalent to the inconsistency of $\textbf{PRA}$.

2. We can from line 1 and 6 infer that a sentence of $\textbf{PRA}$ is equivalent to its own unprovability if and only if it is equivalent to the assertion that $\textbf{PRA}$ is consistent and that a sentence of $\textbf{PRA}$ that is equivalent to the assertion that it is unprovable if it is provable if and only if it is equivalent to the assertion that if the inconsistency of $\textbf{PRA}$ is provable then $\textbf{PRA}$ is provable.

3. From line 10 we can conclude that for arbitrary sentence F and G of $\textbf{PRA}$ that: F is equivalent to the conduction of F is provable and G is true if and only if F is equivalent to the conduction of G is provable and true. Here we take * such that $p^* = F$ and $q^* = G$.

4. From line 6 again we can conclude that a fixed point may have a bigger modal degree, than formula of which it is a fixed point: the formula $\Box p \rightarrow \Box \neg p$ has modal degree 1 and the formula $\Box \Box \bot \rightarrow \Box \bot$ has degree 2. We can conclude the same for line 7, where the fixed point has modal degree 3 and the formula it is a fixed point for has degree 2.

5. The modal formula α has at most the same modal degree as the modal formula σ.

7.6 Implications of Solovays Theorems

The clearest implication of the generalized versions of Solovay's Completeness Theorems is that the proof predicate of arithmetics can be axiomatized; everything there is to say about the predicate, can be deduced from the derivability conditions and Löb's theorem. This can be seen both as a positive and negative result. Positive since the proof predicate follows some simple rules and these rules does not alter even though you add more induction to the fragment of arithmetics you are working with. The last point can also be seen as a negative one; there is no way to differentiate the different fragments of arithmetics by looking at their proof predicate.

Further the proportional provability logic is not "hit" with Quines critique of modal logic as being unintelligible, since it has a very clear and unambiguous arithmetic interpretation.

8 Further Results in Provability Logic

In this chapter we will enrich the language $\mathcal{L}_\square$ with both more modal operators and quantifiers. For these language a number of different results can be proven. This chapter will skip the most of the proofs of these results, but the proofs can be found in George. S Boolos 1993.

8.1 Multi-modal provability logic

We can extend our language $\mathcal{L}_\square$ with more modality operators. We will start of by extending it with the modal operator: ⊡ and its dual ◈. In the next subsection it will be explained what we will mean with the ⊡. Latter on we will extend the language with even more modal operators.

8.1.1 The system GLB

Definition 8.1 We will say that a theory **T** is ω-inconsitsent iff for some formula $\alpha(x)$, **T** $\vdash \exists x \alpha(x)$ and for every $n \in \omega$ we have: **T** $\vdash \neg\alpha(x)$. **T** is called ω-consistent iff it is not ω-inconsistent. ⊣

We have that if **T** is ω-consistent then **T** $\nvdash \exists x x \neq x$ and thus **T** is consistent. So ω-consistency implies consistency; but the converse does not hold.

Definition 8.2 A sentence α is ω-inconsistent in **T** if the axioms of **T** plus α is ω-inconsistent. α is ω-consistent iff it is not ω-inconsistent.

We further say that a sentence α is ω-provable in **T** iff $\neg\alpha$ is ω-inconsistent with **T**. ⊣

It is clear that if α is provable in **T** then it is ω-provable in **T**. We will introduce a new modal system **GLB**, where **B** stands for bimodal, where we add two new modal operators: ⊡ and ◈ to our modal language $\mathcal{L}_\square$. We will call this new language for $\mathcal{L}_⊡$

Definition 8.3 The langauge $\mathcal{L}_⊡$ is the language $\mathcal{L}_\square$ extend with the modal operator ⊡, where the syntax ⊡ is the same as that of $\square$. The operator ◈ is defined as the dual of ⊡ ⊣

77

We now define the system of **GLB**. We will later on discuss the semantics of **GLB**, but this is not of important right now.

Definition 8.4 The axioms of **GLB** are all tautologies and all sentences of the following kind:

A1 $\Box(\alpha \to \beta) \to (\Box\alpha \to \Box\beta)$

A2 $\boxdot(\alpha \to \beta) \to (\boxdot\alpha \to \boxdot\beta)$

A3 $\Box(\Box\alpha \to \alpha)\Box\alpha$

A4 $\boxdot(\boxdot\alpha \to \alpha)\,\boxdot\alpha$

A5 $\Box\alpha \to \boxdot\alpha$

A6 $\neg\Box\alpha \to \boxdot\neg\Box\alpha$

MP Modus ponens

Nec $\Box$-necessitation; from α infer $\Box\alpha$.

$\dashv$

It is clear that $\boxdot$-necessitation is a rule of **GLB**, since we have that if **GLB** $\vdash \alpha$ then **GLB** $\vdash \Box$ and by A5 we then have **GLB** $\vdash \boxdot\alpha$.

The next goal is to prove an arithmetical soundness theorem for **GLB**. For this end we need the following definition:

Definition 8.5 We call the following rule for the *ω-rule*: Infer $\forall x\alpha(x)$ for all $\alpha(\overline{n})$, where $n \in \omega$. A sentence is provable under the ω-rule in **T** if it belongs to all classes containing the axioms of **T** and closed under MP, Nec and the ω-rule. We further say that a sentence F is provable in **PRA** by *one application of the ω-rule* if for some formula $G(x)$ we have that **PRA** $\vdash G(\overline{n})$ for all n and **PRA** $\vdash \forall xG(x) \to F$. $\dashv$

It can be shown that a sentence F is ω-provable if and only if it is provable by one application of the ω-rule. With this we can define the notion of an ω-proof.

Definition 8.6 A sentence $\forall xG(x) \to F$ is called an *ω-proof* prof of F if **PRA** $\vdash G(\overline{n})$ for all n and **PRA** $\vdash \forall xG(x) \to S$. $\dashv$

It is clear that if F has an ω-proof then it ω-provable.

We will state one last definition in the same vein as the others above:

Definition 8.7 **PRA**$^+$ is the theory extending **PRA** with all sentences $\forall xG(x)$ such that for every $n \in \omega$ we have that **PRA** $\vdash G(\overline{n})$. $\dashv$

The following theorem can then be proven about the relationships between the above definitions:

Theorem 8.1 The following are equivalent:

1. F is ω-provable.

2. $\mathbf{PRA}^+ \vdash F$.

3. F is provable by one application of the ω-rule.

4. There is an ω-proof of F.

We need a few more definitions before we can state the arithmetical soundness theorem for **GLB**:

Definition 8.8 Let $\omega\mathrm{Prov}(y, x)$ be the formula of **PRA** the formalizes that y is the code of an ω-proof of x, and let $\omega\mathrm{Pr}(x) = \exists y \omega\mathrm{Prov}(y, x)$ ⊣

We then have that $\omega\mathrm{Pr}(x)$ by theorem 8.1 is provable coextensive with the formulas stating in **PRA** the following properties: "ω-provable", "provable in **PRA**$^+$ and "provable by one application of the ω-rule". This means that for each sentence F in **PRA** that we have:

$$\mathbf{PRA} \vdash \mathrm{Pr}(\ulcorner F \urcorner) \rightarrow \omega\mathrm{Pr}(\ulcorner F \urcorner)$$

With these results we can now extend the interpretation of $\mathcal{L}_\Box$ in **PRA** to one of $\mathcal{L}_{[1]}$:

Definition 8.9 An interpretation * of $\mathcal{L}_{[1]}$ in **PRA** is an extension of an interpretation $\mathcal{L}_\Box$ in **PRA** where we add the following:

$$[1](\alpha)^* = \omega\mathrm{Pr}(\ulcorner \alpha^* \urcorner)$$

⊣

We can now state the arithmetical soundness theorem for **GLB**:

Theorem 8.2 (The aritmetical soundness theorem for **GLB**) For any modal formula α and interpretation of $\mathcal{L}_{[1]}$ in **PRA** we have that:

$$\vdash_{\mathbf{GLB}} \alpha \rightarrow \ \mathbf{PRA} \vdash \alpha^*$$

We omit the proof here. We can not prove the arithmetical completeness theorem for **GLB** without the help of another multi modal logic.

This is because there is no good Kripke semantics for the logic **GLB**. We will start of by defining a Kripke modal for the logic **GLB**; this definitions is a extension of a "normal" frame, but with two relations instead of one

Definition 8.10 A frame for a modal logic with two modal operators is a triple $\mathcal{H} = \langle W, R, R_1 \rangle$ where both R and R_1 are relations on W. A model is a quadruple $\mathcal{K} = \langle W, R, R_1, \phi \rangle$ were ϕ is a valuation function on W. The truth of modal formula α in a given node $w \in W$ is defined in the obvious way, and the two main clauses of the definition is:

1. $\vdash^{\mathcal{K}}_w \Box\alpha$ iff for all $v \in W$ such that wRv we have $\vdash^{\mathcal{K}}_v \alpha$

2. $\vdash^{\mathcal{K}}_w \boxdot\alpha$ iff for all $v \in W$ such that wR_1v we have $\vdash^{\mathcal{K}}_v \alpha$

$\dashv$

The problem here for is that no matter what the relation R_1 will be the empty relation W and therefor $\boxdot\bot$ will be valid and thus contradict that $\vdash_{\textbf{GLB}}\boxdot\bot$ from the arithmetical soundness of **GLB**. Giorgie Dzhaparidze found a way around this by looking at another multi modal logic, which will be introduced in the next section. His result was improved by Konstantin Ignatiev .

8.1.2 The system IDzh and completeness of GLB

Since **GLB** does not have any good Kripke semantic we will at a multi modal logic that has such a semantic; we will call this modal logic for **IDzh** Ignatiev and Dzhaparidze.

Definition 8.11 The language of **IDzh** is the same as **GLB**. Further the axioms of **IDzh** are all tautologies and the following modal formulas:

A1 $\Box(\alpha \rightarrow \beta) \rightarrow (\Box\alpha \rightarrow \Box\beta)$

A2 $\boxdot(\alpha \rightarrow \beta) \rightarrow (\boxdot\alpha \rightarrow \boxdot\beta)$

A3 $\Box(\Box\alpha \rightarrow \alpha) \rightarrow \Box\alpha$

A4 $\boxdot(\boxdot\alpha \rightarrow \alpha) \rightarrow \boxdot\alpha$

A5 $\Box\alpha \rightarrow \boxdot\Box\alpha$

A6 $\neg\alpha \rightarrow \boxdot\neg\Box\alpha$.

MP Modus pones

Nec $\Box$-necessitation

Nec$_1$ $\boxdot$-necessitation

Here we add the inference Nec_1 since this rule can not be proven from the other rules and axioms in this modal logic. ⊣

The modal logic **IDzh** can be shown to be weaker than **GLB** and thus **IDzh** ⊆ **GLB**.

The multi modal logic **IDzh** has the following Kripke semantic for which a soundness and completeness theorem can be proven.

Definition 8.12 An **IDzh**-model is a quadruple $\mathcal{K} = \langle W, R, R_1, \phi \rangle$, where W is a finite non-empty set, ϕ is a valuation function W, and R and R_1 are transitive irreflexive relation on W such that for all $w, v_1, v_2 \in W$ we have that:

$$\text{If } wR_1v_1 \text{ then } wRv_2 \text{ if and only if } v_1Rv_2$$

⊣

This means that we can not have that wRv and wR_1v since then vRv; contradicting the irreflexivity R

For such models the following theorem can be proven:

Theorem 8.3 α is valid in all **IDzh**-models if and only if $\vdash_{\textbf{IDzh}} \alpha$.

This theorem shows that **IDzh** has a natural Kripke semantic to which it is sound and complete.

We will need the following definitions to state the theorem from which the arithmetical completeness theorem for **GLB** follows:

Definition 8.13 For any modal formula α we define $\Delta\alpha$ as the formula:

$$\alpha \wedge \Box\alpha \wedge \boxed{1}\,\alpha \wedge \Box\,\boxed{1}\,\alpha$$

We define the formula $\Psi\alpha$ as:

$$\bigwedge_{\Box\beta \in S(\alpha)} \Delta(\Box\beta \to \boxed{1}\beta)$$

⊣

It is clear that $\vdash_{\textbf{GLB}} \Psi\alpha$ To show completeness of **GLB** the following three statements should be proven to be equivalent:

1. $\vdash_{\textbf{IDzh}} \Psi\alpha \to \alpha$

2. $\vdash_{\textbf{GLB}} \alpha$

3. $\textbf{PRA} \vdash \alpha^*$ for all *

We have that (1) $\Rightarrow$ (2) since **IDzh** $\subset$ **GLB** and the fact that $\vdash_{\textbf{GLB}} \Psi\alpha$. That (2) $\Leftrightarrow$ (3) is just the arithmetical soundness theorem for **GLB**. The proof of (3) $\Rightarrow$ (1) will obviously prove the arithmetical completeness theorem for **GLB**. The proof of this can be found in George. S Boolos 1993 and is beyond the scope of this project.

8.1.3 The system GLP

We will end this section by introducing the system **GLP** The language $\mathcal{L}_{[n]}$ of **GLP** is an extension of $\mathcal{L}_\square$, where instead of $\square$ we write $[0]$ and we furhter add a countable infinite amount of boxes: $[1], [2], \ldots$ representing provability in $\textbf{PRA}^+$, $\textbf{PRA}^{++}$ and so on, where $\textbf{PRA}^{++}$ is $\textbf{PRA}^+$ with all formulas of the form $\forall x G(x)$ such that for every $n \in \omega$ such that $\textbf{PRA}^+ \vdash G(\overline{n})$ added. We define their duals $\langle 0 \rangle, \langle 1 \rangle, \langle 2 \rangle, \ldots$ in the obvious way and these represent consistency, ω-consistency, ω-ω-consistency and so on. We can now define the system **GLP**:

Definition 8.14 The axioms and inferences rules of **GLP** are the following:

   A1 $[n](\alpha \to \beta) \to ([n]\alpha \to [n]\beta)$

   A2 $[n]([n]\alpha \to \alpha) \to [n]\alpha$

   A3 $[n]\alpha \to [n+1]\alpha$

   A4 $\neg[n]\alpha \to [n+1]\neg[n]\alpha$

 MP Modus Ponens

Nec$_0$ $[0]$-necessiation

$\dashv$

Following Dzhaparidze the arithmetical completeness theorem can be proven for this system of multi modal logic. The proof follows that of the proof of the arithmetical completeness theorem for **GLB**.

8.2 Quantifed provability logic

There is another way to extend the logic **GL**; we can add quantifiers to the language. We will call this logic for quantified modal logic (QML). The first goal is to define what a formula is:

Definition 8.15 α is a formula of QML if and only if it can be obtained from a formula of first order logic by replacing occurrences of the negation sign "$\neg$" with occurrences of $\square$. $\dashv$

There is not a version of Solovay's completeness theorems for this logic; i.e it is not arithmetically complete with respect to any fragment of arithmetics. Furthermore this logic do not have the fixed point property and is not complete with respect to any class of Hintikka frames. Further information on this topic can be found i George. S Boolos 1993
